**(Directed by Professor Joo-Heon Yoon)**

Increasing evidence suggests that P2 receptors (P2Rs) in airway epithelial cells perform critical functions in auto- or paracrine regulation of fluid and mucus secretion. In the present study, we characterized the effects of P2R stimulation on Na<sup>+</sup>-K<sup>+</sup>-2Cl<sup>-</sup> cotransporter (NKCC) in normal human nasal epithelial (NHNE) cells. [Ca<sup>2+</sup>]<sub>i</sub> and pH<sub>i</sub> were measured in primary cultures of NHNE cells using a double perfusion chamber, which enabled us to analyze membrane-specific transporter activities. NKCC activities were estimated by the pH<sub>i</sub> reduction due to Na<sup>+</sup>-dependent and bumetanide-sensitive intracellular uptake of NH<sub>4</sub><sup>+</sup>. NKCC activities were observed in the

basolateral membrane, but not in the luminal membrane of NHNE cells. Interestingly, P2Rs were expressed in both membranes, and the stimulation of either luminal or basolateral P2R increased NKCC activity. Blockades of luminal Cl<sup>-</sup> channels, basolateral K<sup>+</sup> channels, or protein kinase C did not affect the activation of NKCC by basolateral P2R stimulation. The effects of luminal P2R stimulation were partially reduced by Cl<sup>-</sup> channel blockers. However, chelation of intracellular Ca<sup>2+</sup> by 1,2-bis(2-aminophenoxy)ethane-*N,N,N',N'*-tetraacetic acid (BAPTA) treatment completely blocked the stimulatory effects of luminal and basolateral P2Rs on NKCC. In addition, increasing [Ca<sup>2+</sup>]<sub>i</sub> by treatment with ionomycin- stimulated NKCC activity. These results provide evidence that stimulation of P2Rs directly activates basolateral NKCC by Ca<sup>2+</sup>-dependent pathways in NHNE cells, which is an important aspect of the purinergic regulation of ion and fluid secretions in human airway epithelia under physiologic and pathologic conditions.

**I. INTRODUCTION**

The mucosal surfaces of airway tract are covered with airway surface fluid (ASF), which performs critical roles in proper functioning of airway tracts and in protecting the lining epithelia<sup>1-3</sup>. The hypersecretion or the contraction of ASF is associated with a wide spectrum of respiratory tract diseases from allergic rhinitis to cystic fibrosis (CF). Chronic volume contraction, either by defects in secretion or by dysregulated hyper-absorption, induces the formation of hyper-viscous mucus, which is thought to be the underlying pathogenic mechanism of CF<sup>1,2</sup>. On the other hand, in stimulated

conditions such as in allergic inflammation, airway epithelia actively secrete ion and fluids by locally induced neurotransmitters and inflammatory mediators<sup>4</sup>.

It is generally accepted that transepithelial Cl<sup>-</sup> transport is the major driving force for fluid secretions in airway epithelia<sup>5,6</sup>. During past decades, extensive investigations have been performed on the molecular nature and the regulatory mechanisms accounting for this important biologic process. However, most of the studies focused on the luminal Cl<sup>-</sup> exit pathways, especially on the transporter named cystic fibrosis transmembrane conductance regulator (CFTR), in which gene mutation causes CF and other related disorders<sup>7,8</sup>. Equally important process is the basolateral Cl<sup>-</sup> uptake pathways. In fact, recent evidence suggested that the activities of basolateral Na<sup>+</sup>-K<sup>+</sup>-2Cl<sup>-</sup> cotransporter (NKCC) are the rate-limiting step of ion and fluid secretions in Cl<sup>-</sup> secreting epithelia<sup>6,9</sup>. In addition to NKCC, several other mechanisms can mediate intracellular Cl<sup>-</sup> uptake: 1) the parallel activation of Na<sup>+</sup>/H<sup>+</sup> and Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchangers; 2) other members of cation-chloride cotransporters such as K<sup>+</sup>-Cl<sup>-</sup> cotransporter (KCC) and Na<sup>+</sup>-Cl<sup>-</sup> cotransporter (NCC); and 3) a Cl<sup>-</sup>-ATPase. However, these transporters are expressed in specific tissues or are active in specific conditions, whereas NKCC is known to be ubiquitously expressed and responsible for most of the intracellular Cl<sup>-</sup>

uptake in the secretory epithelia<sup>5</sup>. To date, two isoforms of NKCC were identified, NKCC1 and NKCC2. Both belong to the cation-chloride cotransporter family, which has 12 membrane-spanning domains<sup>5,10</sup>. Among them, NKCC1 is in general expressed in the basolateral membrane of Cl<sup>-</sup> secreting epithelia<sup>5,6</sup>.

As in other CFTR- and NKCC1-expressing epithelial tissues, cells in the airway tract are under control of several agonists, which include agonists in the cholinergic and adrenergic systems. Recently, the purinergic system, a different type of regulating systems, has attracted increasing attention in the regulation of transepithelial transport due to its unique properties<sup>3</sup>. For example, purinergic receptors (P2Rs) are expressed in the luminal membrane as well as in the basolateral membrane of many epithelial cells<sup>11,12</sup>. In addition, accumulating evidence suggests that activations of P2Rs is not only involved in the regulation of physiologic function but also associated with pathologic conditions<sup>3</sup>. Therefore, a dissection of the effects of P2R on the basolateral Cl<sup>-</sup> uptake pathways would improve our understanding of physiological and pathological regulations of airway secretions.

We employed primary cultures of normal human nasal epithelial (NHNE) cells as a model of human airway epithelia. Alterations in nasal secretion are frequently associated with common medical problems such as

allergic rhinitis or the common cold<sup>4</sup>. In addition, cells in nasal mucosa share some common features with cells in other airway epithelia in both morphological and molecular aspects. For example, nasal epithelia have cilia on the luminal surface and co-express CFTR and epithelial Na<sup>+</sup> channel (ENaC) on the luminal membrane, similar to cells in the middle or lower airway tract<sup>13</sup>. Therefore, an investigation of the nasal secretory mechanism itself has significant clinical meanings, and further, the results may be extrapolated to the secretory mechanisms of cells in the middle and lower airway tracts.

In the present study, we analyzed the effects of P2R activation on NKCC in human nasal epithelia. NKCC activities were observed only in the basolateral membrane of NHNE cells and immunoblotting using specific antibodies revealed the expression of NKCC1. Interestingly, P2Rs were expressed in both luminal and basolateral membranes, and the stimulation of either luminal or basolateral P2R increased the basolateral NKCC activity. Finally, the stimulatory effects of P2R on NKCC were completely dependent on intracellular Ca<sup>2+</sup> signals. These findings will provide the basis for understanding the purinergic control of secretions in human nasal and airway epithelia under physiologic and pathologic conditions.

## II. MATERIALS AND METHODS

### 1. Chemicals and Solutions

The fluorescent probes, Fura-2-AM and 2',7'-bis(2-carboxyethyl)-5(6)-carboxyfluorescein (BCECF-AM), and the intracellular  $\text{Ca}^{2+}$  chelator 1,2-bis(2-aminophenoxy)ethane-*N,N,N',N'*-tetraacetic acid acetoxymethyl ester (BAPTA-AM) were purchased from Molecular Probes (Molecular Probes, Eugene, OR, USA). The  $\text{Cl}^-$  channel blocker 5-nitro-2-(3'phenylpropyl-amino)benzoic acid (NPPB) was obtained from Alexis (Alexis, Carlsbad, CA, USA), and 4,4'-diisothiocyanatostilbene-2,2'-disulfonic acid disodium salt (DIDS) was from Calbiochem (Calbiochem, San Diego, CA). Ammonium gluconate was purchased from Pfaltz & Bauer (Pfaltz & Bauer, Waterbury, CT, USA). All other chemicals including ATP, ouabain, bumetanide,  $\text{BaCl}_2$ , Go 6976, and rottlerin were purchased from Sigma (Sigma, St. Louis, MO, USA).

The standard HEPES-buffered perfusate was termed solution A and contained (in mM) 140 NaCl, 5 KCl, 1  $\text{MgCl}_2$ , 1  $\text{CaCl}_2$ , 10 D-Glucose, and 10 HEPES (pH 7.4 with NaOH). The  $\text{Na}^+$ -free solution B was prepared by replacing  $\text{Na}^+$  with *N*-methyl-D-glucamine<sup>+</sup> (NMDG) from solution A (pH 7.4 with Tris). The  $\text{Cl}^-$ -free solution C contained (in mM) 140  $\text{Na}^+$ -gluconate, 5

K<sup>+</sup>-gluconate, 1 MgSO<sub>4</sub>, 9.3 hemicalcium cyclamate, 10 D-glucose and 5 HEPES (pH 7.4 with NaOH). In the measurements of NH<sub>4</sub><sup>+</sup> uptake, 20 mM of Na<sup>+</sup> or *N*-methyl-D-gluconate<sup>+</sup> was replaced with equimolar NH<sub>4</sub><sup>+</sup> using NH<sub>4</sub>Cl or NH<sub>4</sub><sup>+</sup>-gluconate in each solution. The osmolarity of all solutions was adjusted to 310 mosM with the major salt prior to use.

## **2. Culture of NHNE cells**

Primary cultures of NHNE cells were prepared as described previously<sup>14,15</sup>. All procedures were approved by the Institutional Review Board of Yonsei Medical Center. Passage-2 NHNE cells were plated on a collagen-coated semipermeable membrane with a 0.45- $\mu$ m pore size (Transwell-clear; Costar Co., Cambridge, MA, USA) at a density of  $1.0 \times 10^4$  cells/cm<sup>2</sup> for intracellular pH (pH<sub>i</sub>) and [Ca<sup>2+</sup>]<sub>i</sub> measurements. The cells were maintained in 1:1 mixture of bronchial epithelial growth medium and Dulbecco's modified Eagle's medium containing 10% fetal bovine serum and all supplements<sup>14</sup>. Membranes bearing cultured cells (culture area, 0.3 cm<sup>2</sup>) were floated on the culture medium in Petri dishes and incubated for 4-5 days until the cells formed a functionally polarized monolayer.

## **3. Measurement of [Ca<sup>2+</sup>]<sub>i</sub>**

$[Ca^{2+}]_i$  levels in the monolayers were determined using protocols reported previously with slight modification<sup>16</sup>. Briefly, after achieving confluency, the cells were loaded with Fura-2 by incubating in a medium containing 3  $\mu$ M Fura-2-AM and 1.6  $\mu$ M pluronic F127 (for 30 min, at 37°C). A membrane bearing Fura-2-loaded cells was mounted in a miniature Ussing chamber (AKI Institute, University of Copenhagen, Copenhagen, Denmark) attached to the stage of an inverted microscope. The membrane was located between the two-half chambers, which separated the chamber into a luminal (upper) and a basolateral (lower) compartment. A transparent coverslip was placed at the bottom of the perfusion chamber, which allowed fluorescence measurements from the dye-loaded monolayers using objective lenses having a long working distance (more than 2 mm). Separate luminal and basolateral perfusates were delivered to the chamber after warming (37 °C). Fura-2 fluorescence was recorded (Delta Ram; PTI Inc., South Brunswick, NJ, USA) at excitation wavelengths of 350 and 380 nm, and the 350/380 fluorescence ratio was calibrated by exposing the cells to solutions containing high and low concentrations of  $Ca^{2+}$  and 10  $\mu$ M ionomycin.

#### **4. Measurements of Intracellular pH ( $pH_i$ ) and NKCC activity**

$pH_i$  was measured in the monolayers using the pH-sensitive fluorescent

probe BCECF. Cells were loaded with BCECF for 10 min at room temperature in solution A containing 2.5  $\mu\text{M}$  BCECF-AM and mounted in the miniature Ussing chamber described for  $[\text{Ca}^{2+}]_i$  measurements. BCECF fluorescence was recorded and calibrated using a previously described protocol<sup>16</sup>. Briefly, the fluorescence at excitation wavelengths of 490 and 440 nm was recorded using a recording setup (Delta Ram; PTI Inc.), and the 490/440 ratios were calibrated intracellularly by perfusing the cells with solutions containing 145 mM KCl, 10 mM HEPES, and 5  $\mu\text{M}$  nigericin with the pH adjusted to 6.2–7.6.

$\text{Na}^+\text{-K}^+\text{-2Cl}^-$  cotransporter activity was estimated from the  $\text{pH}_i$  decrease caused by the intracellular uptake of  $\text{NH}_4^+$  using the methods of Evans and Turner<sup>17</sup> with modifications. As shown in Fig. 1, when challenged with 20 mM  $\text{NH}_4\text{Cl}$  solutions, cells were rapidly alkalinized (0–2 s) due to the intracellular diffusion of  $\text{NH}_3$ . Then, if the cells have  $\text{NH}_4^+$ -transporting machineries, the  $\text{pH}_i$  of the cells would be decreased due to the intracellular uptake of  $\text{NH}_4^+$ . As detailed under “Results,” most of the intracellular  $\text{NH}_4^+$  uptake measured in ouabain (100  $\mu\text{M}$ ) and  $\text{Na}^+$  (140 mM)-containing perfusates was a function of NKCC in NHNE cells. Typically, the first 10–40 s of the initial linear portion of  $\text{pH}_i$  decreases due to  $\text{Na}^+$ -dependent and ouabain-insensitive intracellular  $\text{NH}_4^+$  uptake (shorter times were used for

more rapid decreases) was fitted to a linear equation using the Felix software (version 1.4; PTI Inc.).

Buffer capacity of NHNE cells was calculated by measuring  $\text{pH}_i$  in response to 5-40 mM  $\text{NH}_4\text{Cl}$  pulses in  $\text{Na}^+$ -free solutions<sup>18</sup>, which applied to both luminal and basolateral sides simultaneously. In each experiment, the intrinsic buffer capacity ( $\beta_i$ ) showed a negative linear relationship with  $\text{pH}_i$  between 6.4 and 7.6. The  $\beta_i$  of NHNE cells at resting state ( $23.1 \pm 1.8$  mM/pH unit at  $\text{pH}_i$  7.2) was not significantly different from that of ATP- stimulated cells ( $25.8 \pm 2.7$  mM/pH unit). Therefore, the results of NKCC activity were expressed as  $\Delta\text{pH}$  unit/min, and this value was directly analyzed without compensating for  $\beta_i$ .

## **5. Immunoblotting**

NHNE cells were grown to confluence in 6-well plates. The cells were lysed with 2x lysis buffer (250 mM Tris-Cl (pH 6.5), 2% SDS, 0.1 mol/liter dithiothreitol, 0.02% bromophenol blue, 10% glycerol). Equal amounts of whole cell lysates were resolved by 6% SDS-PAGE and transferred to a polyvinylidene difluoride membrane (Millipore, Bedford, MA, USA). Membranes were blocked with 5% skim milk in Tris-buffered saline (50 mM Tris-Cl, pH 7.5, 150 mM NaCl) for 2 h at room temperature. This membrane

was then incubated overnight with T4 monoclonal antibody (Developmental Studies Hybridoma Bank, Iowa City, IA, USA) in TTBS (0.5% Tween 20 in Tris-buffered saline). After washing with TTBS, the blot was further incubated for 45 min at room temperature with appropriate secondary antibody (Cell Signaling, Beverly, MA, USA) in TTBS and then visualized using the ECL system (Amersham Biosciences, Buckinghamshire, England).

## **6. Statistical analysis**

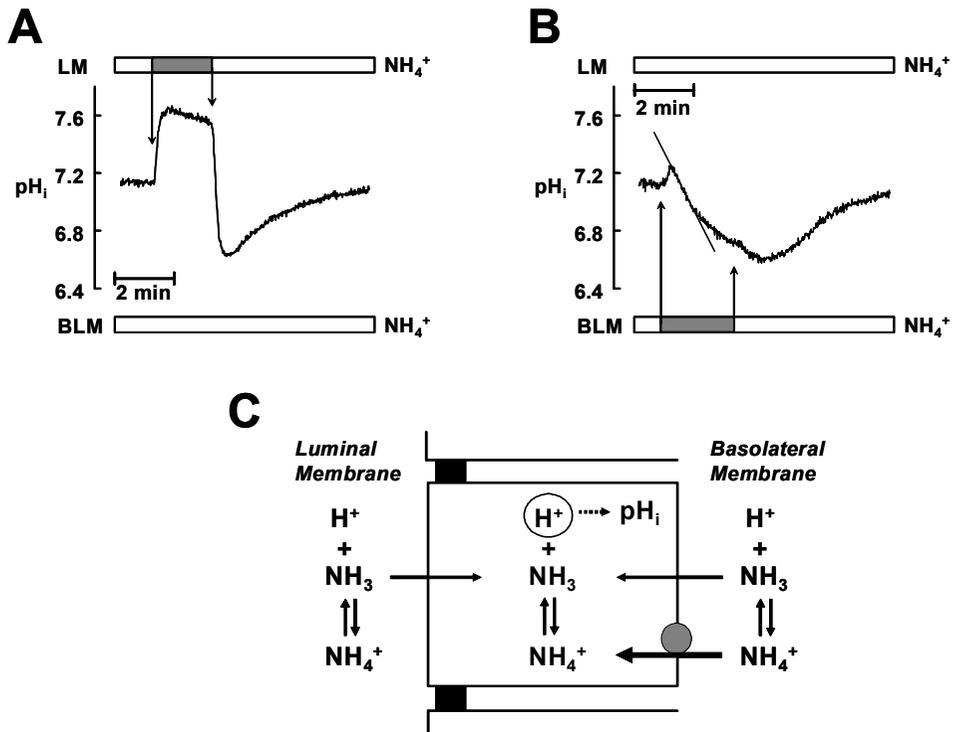

The results of multiple experiments are presented as means  $\pm$  S.E. Statistical analysis was carried out by analysis of variance or Student's *t*-test as appropriate.  $P < 0.05$  was considered statistically significant.

### III. RESULTS

#### 1. $\text{NH}_4^+$ transport in NHNE cells

$\text{Na}^+\text{-K}^+\text{-2Cl}^-$  cotransporter activities were measured using  $\text{NH}_4^+$  as a  $\text{K}^+$  surrogate. As an initial step,  $\text{NH}_4^+$  transport in the luminal and basolateral membrane of polarized NHNE cells was measured. The basal  $\text{pH}_i$  of NHNE cells was  $7.15 \pm 0.04$  in Hepes-buffered solution A, and the application of 20 mM  $\text{NH}_4\text{Cl}$  to the luminal side evoked an abrupt increase in  $\text{pH}_i$  followed by a sustained  $\text{pH}_i$  increases (Fig. 1A). These results indicate that only  $\text{NH}_3$  can pass through the luminal membrane of NHNE cells (see Fig. 1C). At pH 7.4 and 37 °C, 20 mM of  $\text{NH}_4\text{Cl}$  solution contains about 0.6 mM  $\text{NH}_3$  ( $\text{pK}_a=8.9$ ). The charged  $\text{NH}_4^+$  ion cannot pass through the lipid bilayer of plasma membrane, whereas non-polar  $\text{NH}_3$  can freely diffuse into the cells. When it enters the cells,  $\text{NH}_3$  rapidly converts into  $\text{NH}_4^+$  by picking up  $\text{H}^+$  until equilibrium is reached. Therefore,  $\text{pH}_i$  increases due to a reduced  $\text{H}^+$  concentration. However, if the cell membrane expresses an  $\text{NH}_4^+$ -transporting protein,  $\text{NH}_4^+$  enters the cells and  $\text{pH}_i$  decreases since  $\text{NH}_4^+$  donates  $\text{H}^+$  to achieve equilibrium with  $\text{NH}_3$  (Fig. 1C). Interestingly, applications of 20 mM  $\text{NH}_4\text{Cl}$  to the basolateral side induced a small  $\text{pH}_i$  increase followed by rapid  $\text{pH}_i$  decreases, which suggests that the basolateral membrane of NHNE cells

have strong  $\text{NH}_4^+$ -transporting activities (Fig. 1B). The average value of initial  $\text{pH}_i$  reduction caused by basolateral challenge with 20mM  $\text{NH}_4\text{Cl}$  was  $0.331 \pm 0.021 \Delta\text{pH}$  unit/min.

**Fig.1.  $\text{NH}_4^+$  transport in the luminal and the basolateral membranes of NHNE cells.**

$\text{pH}_i$  of NHNE cells were measured using BCECF as described in “Materials and Methods.” The membrane-specific  $\text{NH}_4^+$  -transporting activities of

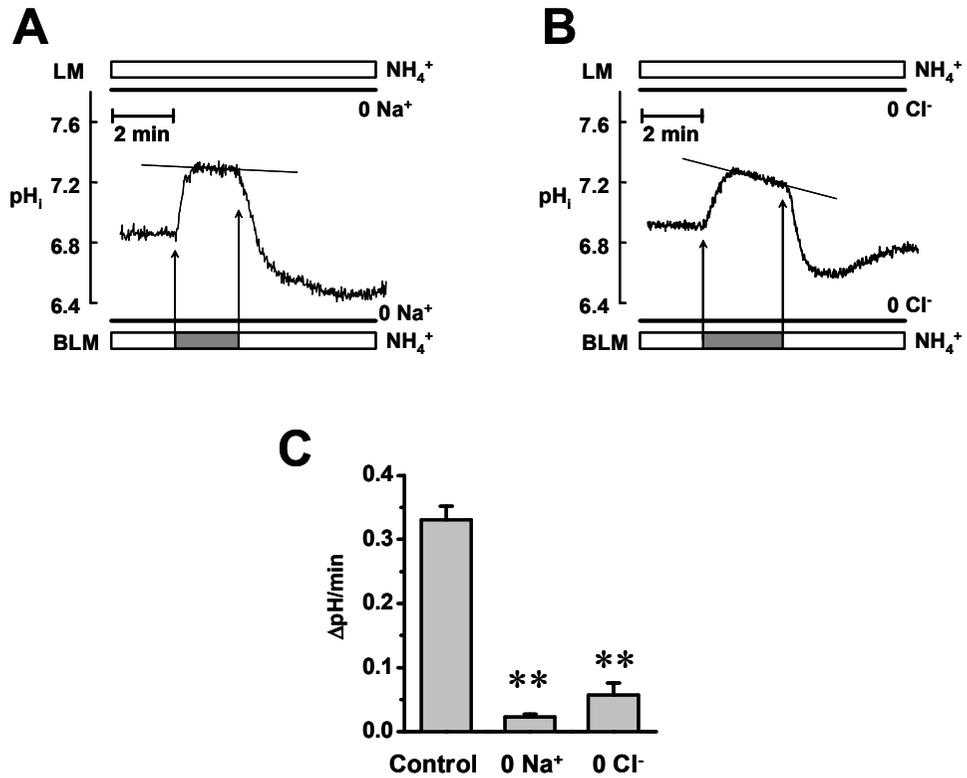

polarized NHNE cells were analyzed using a double perfusion chamber with separate application of  $\text{NH}_4\text{Cl}$  (20 mM). *A*, the application of  $\text{NH}_4\text{Cl}$  to the luminal side evoked an abrupt increase in  $\text{pH}_i$  followed by a sustained  $\text{pH}_i$  increases. *LM*, luminal membrane; *BLM*, basolateral membrane. *B*, the application of  $\text{NH}_4\text{Cl}$  to the basolateral side induced a small  $\text{pH}_i$  increase followed by a rapid  $\text{pH}_i$  decreases. *C*, these results indicate that only non-polar  $\text{NH}_3$  can pass through the luminal membrane of NHNE cells. However, the basolateral membrane of NHNE cells has strong  $\text{NH}_4^+$ -transporting activities (see “Results” for detail).

## **2. Characterization of basolateral $\text{NH}_4^+$ transporting mechanisms**

To date, several transporters are known to transport  $\text{NH}_4^+$ , in particular via  $\text{K}^+$  binding sites<sup>19</sup>. Therefore, we characterized the basolateral  $\text{NH}_4^+$ -transporting activities of NHNE cells. As shown in Fig. 2, we first analyzed the  $\text{Na}^+$  and  $\text{Cl}^-$  dependence of the  $\text{NH}_4^+$ -transporting mechanisms. Incubations of the NHNE cells in the  $\text{Na}^+$ -free solutions for 5 min reduced the basal  $\text{pH}_i$  to  $6.78 \pm 0.07$ . Of interest, the basolateral application of  $\text{NH}_4\text{Cl}$  in  $\text{Na}^+$ -free solutions induced a rapid and sustained  $\text{pH}_i$  increases similar to that observed in the luminal application of  $\text{NH}_4\text{Cl}$  in  $\text{Na}^+$ -containing solutions (Fig. 1A and 2A). Therefore, it was concluded that most of the basolateral  $\text{NH}_4^+$ -

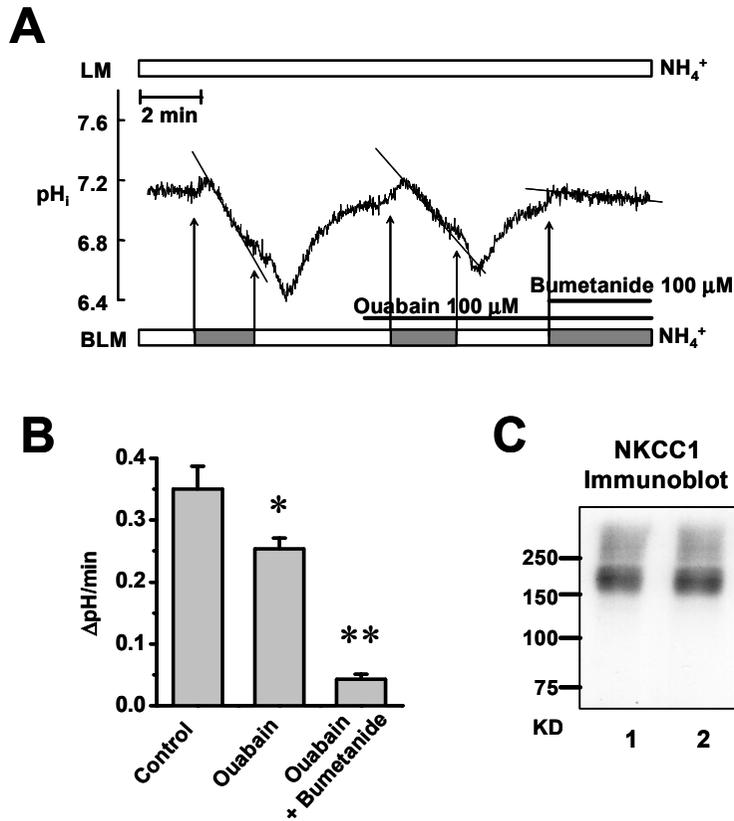

transporting activities are dependent on  $\text{Na}^+$ , which suggests that  $\text{Na}^+$ -independent transporters, such as KCC, do not contribute to the  $\text{NH}_4^+$ -transporting activity. In addition, 83% of the basolateral  $\text{NH}_4^+$  transport was also found to be dependent on  $\text{Cl}^-$  (Fig. 2,B and C).

Basolateral  $\text{NH}_4^+$  transport was further analyzed using inhibitors of  $\text{Na}^+$ - and  $\text{K}^+$ -coupled transporters. As shown in Fig. 3,A and B, the  $\text{Na}^+$ , $\text{K}^+$  ATPase inhibitor ouabain (100  $\mu\text{M}$ ) inhibited the  $\text{NH}_4^+$  transport by 28%, and the addition of the NKCC inhibitor bumetanide (100  $\mu\text{M}$ ) inhibited by 94%. These results and the data concerning  $\text{Na}^+$  and  $\text{Cl}^-$  dependence indicate that NKCC mediates most of the basolateral  $\text{NH}_4^+$  transport in NHNE cells, particularly when treated with ouabain. Subsequently, the expression of NKCC1 in NHNE cells was verified by immunoblotting. Protein extracts of NHNE cells originating from two different individuals showed a band around 170 kDa when blotted with T4 anti-NKCC1 monoclonal antibody, which corresponds to the size of typical glycosylated human NKCC1 (Fig. 3C). In addition, reverse transcriptase-PCR experiments using specific primers of human NKCC1 and NKCC2 revealed that NHNE cells contain only NKCC1 mRNA (not shown).

**Fig.2.  $\text{Na}^+$ - and  $\text{Cl}^-$ -dependence of the basolateral  $\text{NH}_4^+$ -transporting mechanisms.**

The effects of  $\text{Na}^+$  or  $\text{Cl}^-$  removal on the basolateral  $\text{NH}_4^+$  transport were analyzed in NHNE cells. Representative traces of  $\text{Na}^+$  removal or  $\text{Cl}^-$  removal are presented in *A* and *B*, respectively, and a summary (each  $n=5$ ) is shown *C*. Incubations in the  $\text{Na}^+$ -free or in  $\text{Cl}^-$ -free solutions abolished the basolateral  $\text{NH}_4^+$  transport by 96% and 83%, respectively. **\*\* $P<0.01$ :** difference from control.

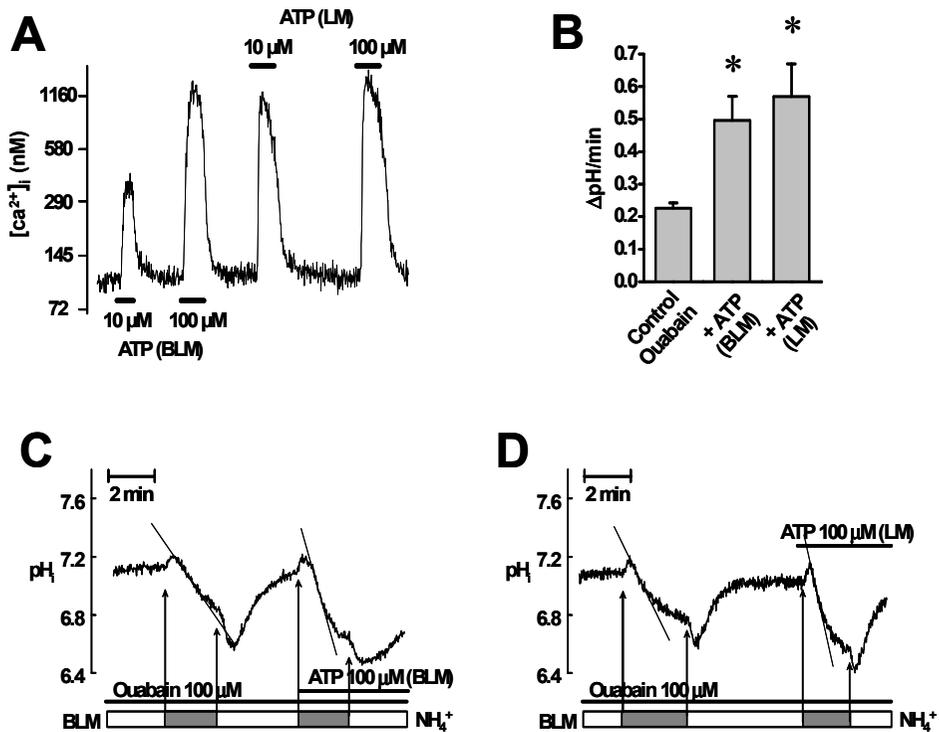

**Fig. 3. Functional and molecular expression of NKCC1 in NHNE cells.**

Basolateral  $\text{NH}_4^+$  transport was measured with solutions containing the  $\text{Na}^+, \text{K}^+$  ATPase inhibitor ouabain and the NKCC inhibitor bumetanide. *A*, a representative trace showing the effects of ouabain ( $100 \mu\text{M}$ ) and bumetanide ( $100 \mu\text{M}$ ). *LM*, luminal membrane; *BLM*, basolateral membrane. *B*, Summarized results of six experiments. *C*, immunoblotting of protein extracts of NHNE cells originating from two separate individuals using T4 anti-

NKCC1 monoclonal antibody. \*P<0.05, \*\*P<0.01, difference from control.

### 3. Activation of NKCC1 by purinergic stimulation

Accumulating evidence suggests that P2 receptors participate in the regulation of transepithelial ion transport in various epithelia<sup>3</sup>. To investigate the effects of P2R on NKCC, we first measured  $[Ca^{2+}]_i$  in response to the membrane-specific applications of P2R agonists. As shown in Fig. 4A, both luminal and basolateral applications of ATP evoked  $[Ca^{2+}]_i$  signals in NHNE cells. Interestingly, P2Rs in the luminal membrane ( $ED_{50}$  for ATP, 4.3  $\mu$ M) showed  $\sim 5$  times higher agonist sensitivity than those of the basolateral membrane ( $ED_{50}$  for ATP, 23.7  $\mu$ M). We next evaluated the effects of P2R stimulation on basolateral NKCC activity using the protocols described above. A summary of the results is presented in Fig. 4B, and representative traces of basolateral ATP and luminal ATP stimulations are shown in Fig. 4, C and D, respectively. Importantly, the stimulation of P2Rs either in the basolateral membrane or in the luminal membrane increased the NKCC activity in NHNE cells. Control basolateral  $NH_4^+$ -transporting activity under ouabain treatment was  $0.223 \pm 0.017$   $\Delta$ pH unit/min, and this value was increased to  $0.496 \pm 0.075$  and  $0.569 \pm 0.102$  by basolateral and luminal ATP applications, respectively.

**Fig. 4. Activation of NKCC by P2R stimulation.**

*A*,  $[Ca^{2+}]_i$  was measured in NHNE cells with basolateral or luminal applications of ATP. *LM*, luminal membrane; *BLM*, basolateral membrane. *B*, summarized results of NKCC measurements with basolateral ( $n=5$ ) or luminal ATP stimulation ( $n=5$ ). *C*, effects of basolateral P2R stimulation on NKCC was measured by comparing the pH decreases ( $\Delta pH$  unit/min) due to intracellular  $NH_4^+$  uptake in control and ATP-stimulated (*BLM*) conditions. To prevent  $Na^+, K^+$  ATPase-mediated  $NH_4^+$  uptake, ouabain ( $100 \mu M$ ) was added

to the basolateral solutions. *D*, effects of luminal P2R stimulation on NKCC were measured using same protocols described in panel *C*, except that ATP was applied to the luminal side. \* $P < 0.05$ : difference from control.

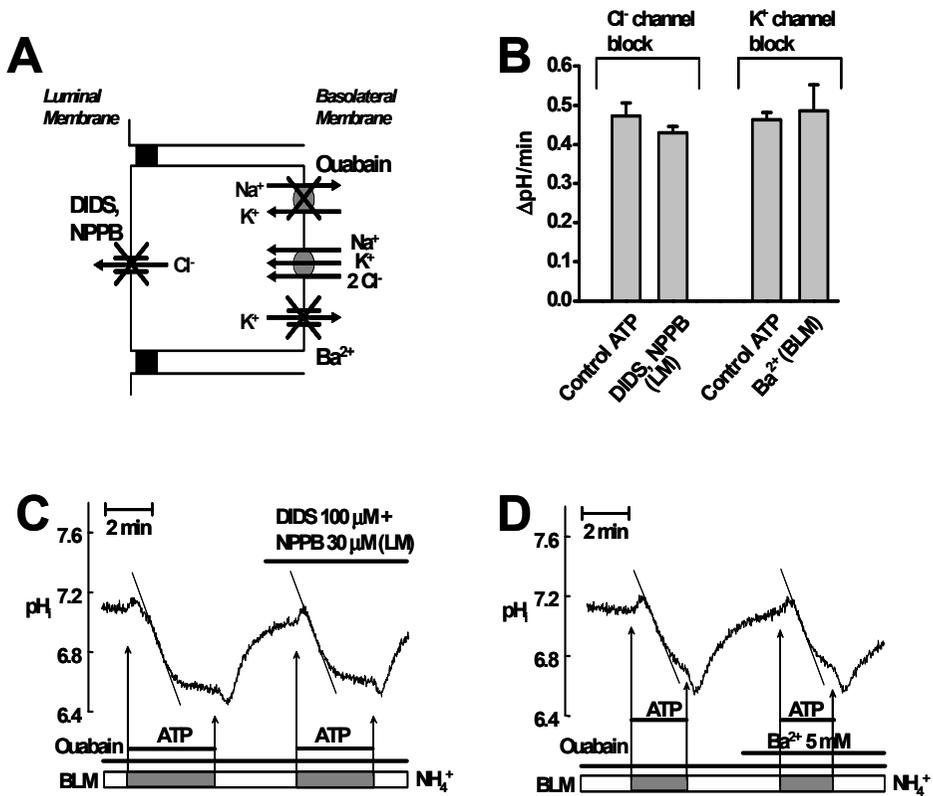

#### **4. Effects of ion channel blockers and PKC inhibitors**

Although we observed that stimulation of either luminal or basolateral P2R activated NKCC, we first analyzed the stimulatory mechanisms of basolateral P2R, which resides in the same membrane as NKCC. Previous studies have reported that various agonists can secondarily regulate NKCC activity by primarily modulating intracellular ionic compositions<sup>5</sup>. In particular, lowering  $[Cl^-]_i$  by the activation of luminal  $Cl^-$  channels and the counter activation of basolateral  $K^+$  channels has been suggested to be an important regulatory mechanism of NKCC<sup>5,20,21</sup>. Therefore, we tested whether the stimulatory effects of basolateral P2R can be inhibited by blockers of  $Cl^-$  or  $K^+$  channels. To block luminal  $Cl^-$  channels, a mixture of the  $Ca^{2+}$ -activated  $Cl^-$  channel (CACC) inhibitor DIDS (100  $\mu M$ ) and of the CFTR inhibitor NPPB (30  $\mu M$ ) was applied to the luminal perfusates (Fig. 5C). As for the basolateral  $K^+$  channels, a non-specific  $K^+$  channel inhibitor  $Ba^{2+}$  (5 mM) was included in the basolateral perfusates (Fig. 5D). As shown in Fig. 5B, neither blockade of the  $Cl^-$  channel nor of the  $K^+$  channel affected the stimulatory

effects of ATP on NKCC. In addition, the blockade of ENaC, which may affect NKCC activity by modulating the membrane potential or  $[Na^+]_i$ , by adding 100  $\mu M$  amiloride to the luminal perfusates did not alter NKCC activity (not shown). Therefore, it was concluded that the increased NKCC activity in response to stimulation of basolateral P2R was due to the intrinsic activation of NKCC.

Recently, it was suggested that the  $\alpha$ -adrenergic agonist methoxamine stimulates NKCC by activating protein kinase C (PKC), in particular, by activating a novel type PKC- $\delta$  isoform in Calu-3 cells originating from human lung adenocarcinoma<sup>22</sup>. The stimulation of P2R, especially the stimulation of G-protein- coupled P2Y receptors, can activate PKC. Therefore, we tested whether the stimulatory effects of P2R on NKCC are dependent on PKC activity in NHNE cells using two types of PKC inhibitors. Cells were pretreated for 30 min with either Go 6976 (500 nM), an inhibitor of classic PKC isoforms, or rottlerin (10  $\mu M$ ), an inhibitor of novel PKC isoforms. NKCC activity was then measured using the luminal and basolateral perfusates containing the same inhibitor concentrations. Unlike the findings observed in Calu-3 cells after methoxamine stimulation<sup>22</sup>, the effects of P2R stimulation in NHNE cells were not inhibited either by Go 6976 or by rottlerin. Basolateral ATP-stimulated NKCC activity after Go 6976 treatment

was  $0.462 \pm 0.059 \Delta\text{pH unit/min}$  ( $n=5$ ), and after rottlerin treatment, it was  $0.443 \pm 0.055$  ( $n=5$ ). These values were not significantly different from the value of basolateral ATP stimulation presented in Fig. 4B ( $0.496 \pm 0.075$ , see above).

**Fig. 5. Effects of Cl<sup>-</sup> and K<sup>+</sup> channel blockers on NKCC activation by basolateral ATP.**

*A*, a diagram of possible secondary activation of NKCC by activations of

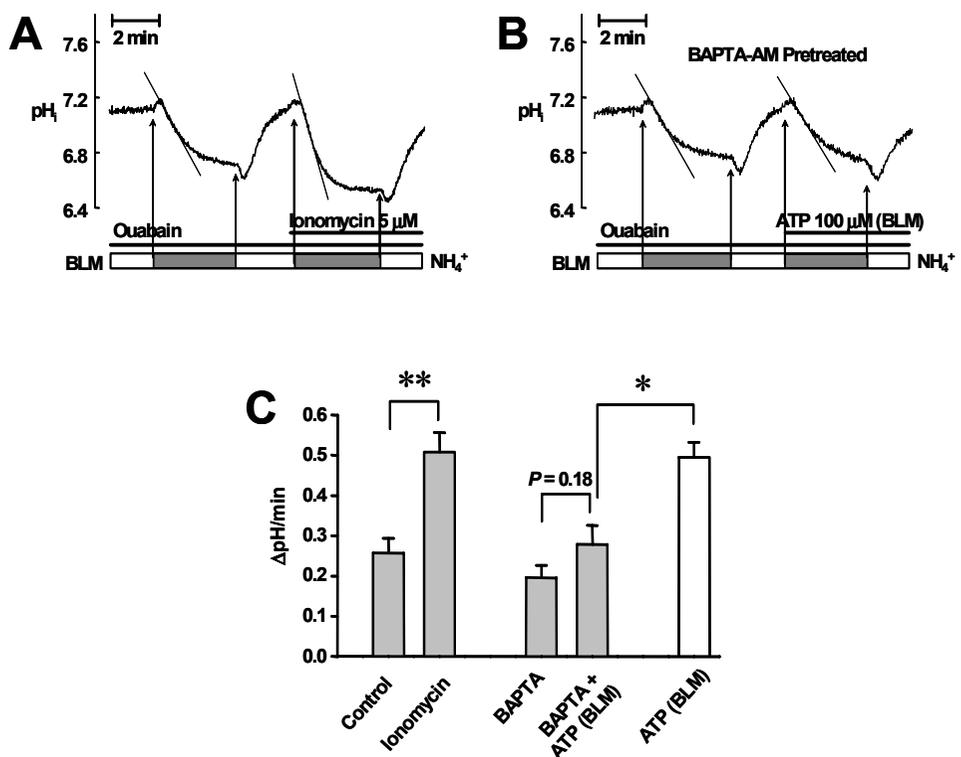

luminal Cl<sup>-</sup> channels and the counter activation of basolateral K<sup>+</sup> channels (see “Results” for details). *B*, summarized results of NKCC measurement with the blockers of Cl<sup>-</sup> channels (n=5) and those of K<sup>+</sup> channels (n=4). *LM*, luminal membrane; *BLM*, basolateral membrane. *C*, the effects of Cl<sup>-</sup> channels blockers were analyzed in basolaterally ATP-stimulated cells. To block luminal Cl<sup>-</sup> channels, the mixture of CACC inhibitor DIDS (100  $\mu$ M) and the CFTR inhibitor NPPB (30  $\mu$ M) was applied to the luminal perfusates. *D*, effects of K<sup>+</sup> channel blockers. To block the basolateral K<sup>+</sup> channels, a non-specific K<sup>+</sup> channel inhibitor Ba<sup>2+</sup> (5 mM) was added to basolateral perfusates.

### **5. The effects of basolateral P2R are dependent on [Ca<sup>2+</sup>]<sub>i</sub>**

As shown in Fig. 4A, either luminal or basolateral ATP evoked a rapid increase in [Ca<sup>2+</sup>]<sub>i</sub>. Therefore, we investigated the role of calcium signals in NKCC activation. First, we measured the effects of [Ca<sup>2+</sup>]<sub>i</sub> increases on NKCC using the Ca<sup>2+</sup> ionophore ionomycin. As shown in Figs. 6A and C, ionomycin treatment (5  $\mu$ M) acutely increased the basolateral NKCC activity by 98%. Next, we investigated whether the calcium signals are required for the P2R-induced activation of NKCC. Surprisingly, the chelation of intracellular Ca<sup>2+</sup> by BAPTA-AM treatment (50  $\mu$ M, for 30 min) almost completely blocked the activation of NKCC by basolateral P2R stimulation

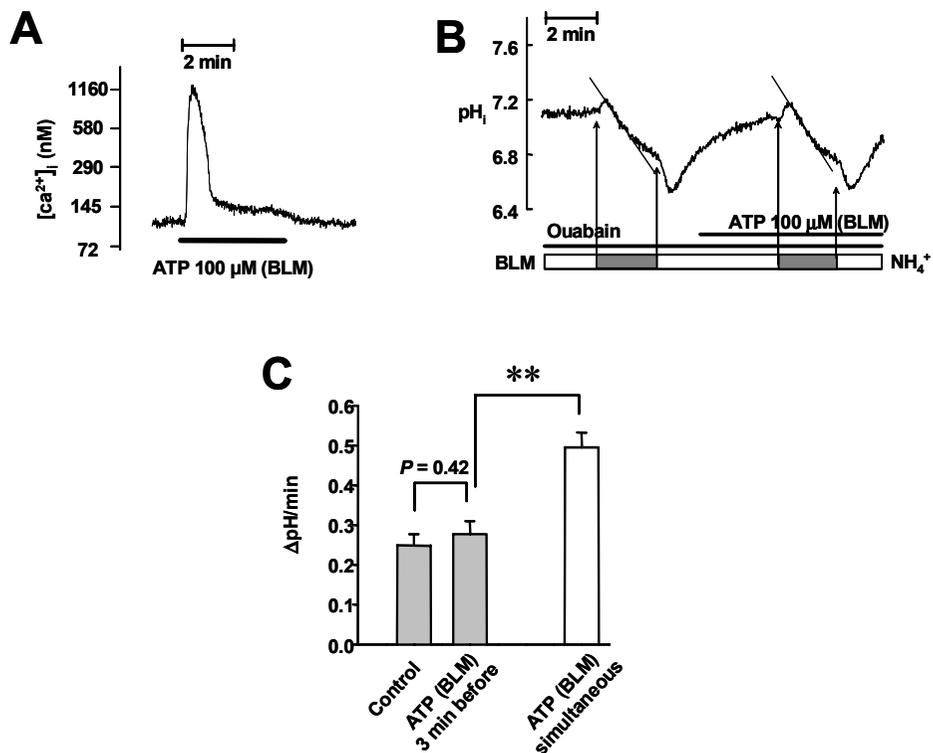

(Figs. 6, B and C).

As depicted in Fig. 7A, stimulation of P2R caused a short-lived  $[Ca^{2+}]_i$  peak followed by a small sustained  $[Ca^{2+}]_i$  increase in NHNE cells. Of interest, treatment with basolateral ATP 3 min before the application of  $NH_4Cl$  solution did not increase the NKCC activity (Figs. 7, B and C). These results suggest that the P2R-induced stimulation on NKCC activity is highly correlated with  $[Ca^{2+}]_i$ .

**Fig. 6.** Role of  $[Ca^{2+}]_i$  in NKCC activation by basolateral ATP.

*A*, NKCC-mediated  $\text{NH}_4^+$  transport was measured with ionomycin treatment ( $5\mu\text{M}$ ). *BLM*, basolateral membrane. *B*, NKCC activities were measured in BAPTA-AM pretreated ( $50\mu\text{M}$ , 30 min) cells. *C*, summarized results of ionomycin ( $n=5$ ) and BAPTA ( $n=7$ ) treatments. Basolateral ATP-stimulated NKCC activity without BAPTA treatment was adopted from Fig.4B. \* $P<0.05$ , \*\* $P<0.01$ , difference from control.

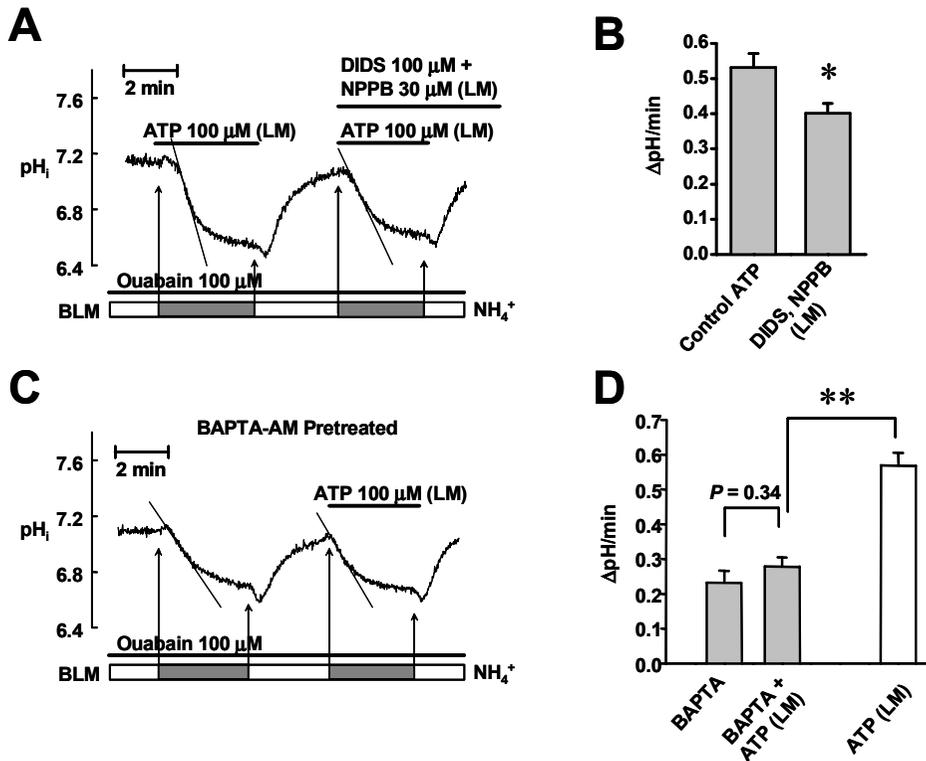

**Fig. 7. Effects of long-term ATP stimulation on the NKCC activity.**

basolateral membrane. *B*, basolateral ATP was applied 3 min before the NKCC measurement. *C*, a summary of the results (n=5). NKCC activity with simultaneous basolateral ATP treatment was adopted from Fig. 4B. \*\*P<0.01: difference from control.

## **6. Characterization of the effects of luminal P2R on NKCC**

The stimulatory effects of luminal P2R on NKCC were analyzed using protocols similar to those used for the investigation of basolateral P2R. As was observed with basolateral ATP, inhibition of ENaC and PKC did not significantly alter the effects of luminal ATP on NKCC (not shown). However, unlike that observed with basolateral ATP, the blockade of luminal Cl<sup>-</sup> channels partially reduced the stimulatory effects of luminal ATP on NKCC (Figs. 8, A and B). The luminal ATP - stimulated NKCC activity was  $0.532 \pm 0.040$  ΔpH unit/min, and this value was decreased to  $0.401 \pm 0.029$  by luminal DIDS and NPPB. Finally, the effects of luminal ATP were measured in the BAPTA-pretreated cells. As illustrated in Figs. 8, C and D, the stimulatory effects of luminal ATP on NKCC were completely blocked by the chelation of intracellular calcium, as was observed in experiments with basolateral ATP.

**Fig. 8. Inhibition of luminal ATP-induced NKCC activation by Cl<sup>-</sup> channel block and by [Ca<sup>2+</sup>]<sub>i</sub> chelation.**

*A*, effects of Cl<sup>-</sup> channel blockers were analyzed in NHNE cells using the protocols described in the legend for Fig. 5 (panel B), except that the cells were stimulated with luminal ATP. *LM*, luminal membrane; *BLM*, basolateral membrane. *B*, a summary of Cl<sup>-</sup> channel block on luminal ATP (*n*=5). *C*, the effects of [Ca<sup>2+</sup>]<sub>i</sub> chelator BAPTA were analyzed in NHNE cells using the protocols described in the legend for Fig. 6 (panel B), except that the cells were stimulated with luminal ATP. *D*, a summary [Ca<sup>2+</sup>]<sub>i</sub> chelation on luminal

ATP (n=5). Luminal ATP -stimulation NKCC activity without BAPTA treatment was adopted from Fig. 4B. \*P<0.05, \*\*P<0.01, difference from control.

#### **IV. DISCUSSION**

Secretion of appropriate fluids is critical in the mucociliary clearance system, which protects the respiratory system from noxious substances. An interesting feature is that airway surface epithelium is capable of releasing ATP and UTP to the luminal space in response to a myriad of physiologic and pathologic stimuli. Moreover, neuroendocrine cells and mast cells along the airway also release ATP to the interstitial space, hence to the basolateral side of surface epithelium, with other agonists from their granules<sup>3,23</sup>. Therefore, purinergic signaling is thought to serve as an important regulatory mechanism of epithelial homeostasis, and to be involved in a number of pathologic conditions.

The present study provides sufficient and necessary evidence that purinergic agonists directly activate basolateral NKCC via calcium signaling in human nasal epithelia. Increased  $[Ca^{2+}]_i$  by ionomycin treatment sufficiently activated the basolateral NKCC in NHNE cells (Fig. 6A). In addition, the finding that  $[Ca^{2+}]_i$  chelation by BAPTA treatment completely

inhibited the P2R-induced effects (Fig. 6B and 8C) demonstrated that calcium signals are required for the P2R-induced activation of NKCC. Previously, it has been shown that an increase in  $[Ca^{2+}]_i$  can modulate NKCC activity in several tissues including airway epithelia<sup>5</sup>. However, most of the studies have suggested that calcium signals do not directly modulate NKCC, but rather affect NKCC activity by secondarily modulating  $K^+$  or  $Cl^-$  conductances<sup>5,20,21</sup>. On the other hand, the present findings that inhibitors of  $Cl^-$  or  $K^+$  channels did not affect the stimulatory effects of basolateral ATP on NKCC (Fig. 5) and only partially inhibited those of luminal ATP (Fig. 8) strongly suggest that purinergic stimulation induced an intrinsic increase in NKCC activity.

One of the basic differences between the present study and previous studies is the method used for determining NKCC activity. We employed a technique that has a high temporal resolution by measuring the real-time changes in  $pH_i$  due to NKCC-mediated intracellular  $NH_4^+$  uptake. Previous studies that have reported only the secondary effects of  $[Ca^{2+}]_i$  used either [ $^3H$ ] bumetanide binding or  $^{86}Rb$  fluxes to determine NKCC activity and measured averaged NKCC activities after long term incubations with agonists<sup>20,21</sup>. For example, Haas *et al.*<sup>20</sup> reported that treatment with luminal ATP for 40 min increased [ $^3H$ ] bumetanide binding by about 80% in canine tracheal epithelia and this increase was almost completely blocked by the  $Cl^-$

channel blocker IAA-94. As shown in the present study, P2R stimulation evoked a short-lasting  $\text{Ca}^{2+}$  peak even in the continuous presence of ATP (Fig. 7). In native tissues, released ATP and UTP are rapidly washed away by the bulk of luminal or interstitial fluids and are instantaneously degraded by ectoenzymes<sup>3,23</sup>. Therefore, repetitive short-lasting P2R stimuli rather than a continuous stimulation would be closer to actual physiological situations. In this regard, our present finding that a short-lasting  $\text{Ca}^{2+}$  peak induced by P2R acutely increases the intrinsic activity of NKCC may have important physiological implications.

A previous study on cholinergic regulation of NKCC in parotid acinar cells reported results that concur with ours (Evans and Turner<sup>17</sup>). These authors also determined NKCC activity by measuring  $\text{pH}_i$  decreases due to NKCC-mediated  $\text{NH}_4^+$  uptake and found the acute up-regulation of intrinsic NKCC activity by the cholinergic agonist carbachol, which was completely inhibited by BAPTA but not by intracellular KCl loss or cell shrinkage. Recently, Brindikova *et al.*<sup>24</sup> reported that long term (30 min) purinergic stimulation inhibits NKCC-mediated  $^{86}\text{Rb}$  fluxes in C11-MDCK cells but not in C7-MDCK cells. However, short term (2 min) purinergic stimulation acutely increased the NKCC activities in both MDCK cell lines, and this was completely inhibited by BAPTA treatment<sup>24</sup>. Together with the present

findings, the above results suggest that the acute activation of NKCC by transient increases in  $[Ca^{2+}]_i$  do not seem to be a phenomenon specific to NHNE cells and that it may be a ubiquitous feature in epithelial tissues.

It is widely accepted that phosphorylation of NKCC1 is related to the increased activity of NKCC1<sup>25,26</sup>. Activities of various kinases such as PKA, PKC and of an unidentified kinase responding to  $[Cl^-]_i$  were suggested to be associated with NKCC1 phosphorylation and activation<sup>5,26</sup>. In fact, it was once reported that the activity of a novel PKC- $\delta$  isoform was required for the methoxamine-induced activation of NKCC1 in Calu-3 cells<sup>22</sup>. However, the present results obtained using PKC inhibitors suggested that the classical and novel isoforms of PKC are not involved in the P2R-induced acute activation of NKCC in NHNE cells. The molecular mechanisms underlying P2R- and  $Ca^{2+}$ -induced activation of NKCC1 require further study.

Previously, we showed that P2R signals evoke the membrane-specific activation of ion transporters in polarized epithelial tissues<sup>27,28</sup>. In the present study, the stimulatory effects of luminal ATP on NKCC were partially inhibited by the blockade of luminal  $Cl^-$  channels (Fig. 8), whereas the stimulatory effects of basolateral ATP were not (Fig. 5). Since the effects of luminal ATP were completely inhibited by chelation of intracellular  $Ca^{2+}$ ,  $Cl^-$  channels responding to  $[Ca^{2+}]_i$  such as CACC are responsible, at least in part,

for the luminal ATP-induced activation of NKCC. The finding that luminal  $\text{Cl}^-$  channels are activated only by luminal ATP but not by basolateral ATP supports the idea of compartmentalized calcium signals in epithelial cells, as suggested by ourselves and by other researchers<sup>11, 27-29</sup>.

## **V. CONCLUSION**

In conclusion, we observed that the stimulation of P2R acutely activated NKCC in NHNE cells. The apical surfaces of airway tract are moistened by airway surface fluid that drives from the transcellular transport of anions, especially  $\text{Cl}^-$  ions. Since the activity of basolateral NKCC, which keeps  $[\text{Cl}^-]_i$  at the levels above the predicted equilibrium potential, is actually the rate-limiting step in epithelial fluid secretion, the results described here add significantly to our understanding of airway secretions in physiologic and pathologic conditions. For example, NKCC activation due to ATP released by activated mast cells may contribute to increased nasal secretions in allergic rhinitis.

Abstract (in Korean)

정상 사람 코점막 상피세포에서  
 $\text{Na}^+\text{-K}^+\text{-2Cl}^-$  Cotransporter 의 발현과 기능

(지도교수 윤 주 현)

연세대학교 대학원 의과학과

신 지 현

여러 연구에서 정상 사람 코점막 상피세포에서 퓨린성 수용체 (P2Rs)가 점액분비의 autocrine과 paracrine 조절에 있어서 결정적인 역할을 한다는 증거가 발견되었다. 본 연구에서 우리는 P2R 의 자극이 정상 사람 코점막 상피세포의  $\text{Na}^+\text{-K}^+\text{-2Cl}^-$  Cotransporter의 활성화에 미치는 영향을 밝혀보았다. 일차 배양한 정상 사람 코점막 상피세포의 세포 내 칼슘이온의 양과 pH는 세포막 특이적 이온 수송체의 활성을 분석할 수 있는 이중관류 chamber 를 이용하여 측정하였다. NKCC 의 기능은  $\text{Na}^+$ 의존적이며 bumetanide 에 민감한 세포 내  $\text{NH}_4^+$  의 유입에 의한 세포 내 pH 의 감소를 통해 예측할 수 있다. NKCC의 기능은 정상 사람 코점막 상피세포의

기저외측막에서 관찰되었으나 관내강막에서는 관찰되지 않았다. 흥미롭게도 퓨린성 수용체는 기저외측막과 관내강막 모두에서 발현하며 어떤 세포막의 퓨린성 수용체를 자극하더라도 NKCC를 활성화시킨다. 관내강막  $\text{Cl}^-$  채널과 기저외측막  $\text{K}^+$  채널, protein kinase C의 억제제는 기저외측막 퓨린성 수용체의 자극에 의한 NKCC 활성화에 영향을 주지 않았으나 관내강막의 퓨린성수용체 자극에 의한 효과는  $\text{Cl}^-$  채널 억제제에 의해 부분적으로 감소하였다. 반면 BAPTA의 처리로 유도된 세포 내 칼슘이온의 킬레이트화는 기저외측막과 관내강막 모두에서 퓨린성 수용체의 효과에 의한 NKCC 자극을 완전히 차단한다. 또한 ionomycin 처리에 의한 세포 내 칼슘이온양의 증가는 NKCC의 기능을 활성화시킨다. 이상의 결과는 정상 사람 코점막 상피에서 퓨린성 수용체의 자극이 칼슘의존적 기저외측막 NKCC를 직접적으로 활성화시킨다는 것을 뒷받침하며, 이는 정상 사람 코점막 상피의 생리적, 병리적 상황에서 퓨린성 수용체에 의한 이온 및 점액분비의 조절이라는 측면에서 중요성을 가진다.
