The publication of genetic epidemiology meta-analyses has increased rapidly, but it has been suggested that many of the statistically significant results are false positive. In addition, most such meta-analyses have been redundant, duplicate, and erroneous, leading to research waste. In addition, since most claimed candidate gene associations were false-positives, correctly interpreting the published results is important. In this review, we emphasize the importance of interpreting the results of genetic epidemiology meta-analyses using Bayesian statistics and gene network analysis, which could be applied in other diseases.

Key words: Systemic lupus erythematosus, False-positive report probability, Bayesian false-discovery probability, STRING database, Protein-protein interaction

Key message

- Bayesian false-discovery probability and false-positive report probability are the 2 major Bayesian methods used to evaluate noteworthiness of a genetic variant.
- Application of stricter *P* value is needed to confirm statistical significance in meta-analyses.
- Gene network analysis of noteworthy genetic variants shows a blueprint of the genetic background in complex diseases.

Introduction

Although the publication of meta-analyses has rapidly increased, researchers have started to determine that many of the statistically significant results are false-positive.^{1,2)} Most such meta-

analyses have redundant duplicate topics and many errors.^{1,3)} Although there has been an impressive increase in meta-analyses from China, particularly those on genetic associations, most claimed candidate gene associations are likely false-positives, suggesting an urgent global need to incorporate genome-wide data and state-of-the-art statistical inferences to avoid a flood of false-positive genetic meta-analyses. In this review, we emphasize the importance of discerning meaningful studies and interpreting their results using Bayesian statistics and gene network analysis. For this purpose, we adopted and reanalyzed significant genes from our previously published systemic meta-analyses of genetic association studies of systemic lupus erythematosus (SLE) as an example.⁴⁾

Current understanding of genetic associations with “noteworthiness”

The traditional interpretation of association studies was labeled as statistically significant by the chosen *P* value of less than 0.05.⁵⁾ Over the past few decades, an unprecedented advance in genotyping technologies has led to a marked increase in the publication of genome-wide association studies (GWAS).⁶⁾ GWAS results generally have much smaller *P* values than those of observational studies, which are expected to have higher numbers of false-positive noteworthy associations. However, in observational studies, the threshold *P* value is generally fixed at 0.05 and the small sample size of studies allows for a *P* value that is highly responsive to a change in the number of cases.⁵⁾ In the case of GWAS, the genome-wide significance threshold should be $P < 5 \times 10^{-8}$.⁷⁾ However, some uncertainty persists about the most appropriate genome-wide significance threshold. At the practical

level, some initial GWAS used a threshold of $P < 1 \times 10^{-7}$.⁸⁻¹⁰ The general rule, however, is that associations with $P < 5 \times 10^{-8}$ are considered replicable.¹¹ And, associations with $P \geq 1 \times 10^{-7}$ are not accepted unless proven by more stringent replication.⁵

Discovering noteworthy variants

The common misunderstanding of the P value is that it is, in fact, not the probability of the null hypothesis being rejected by mistake but the probability of the null hypothesis. Therefore, the evaluation of the hypothesis requires a Bayesian approach that requires prior probability of the hypothesis and the data.¹² To date, 2 major Bayesian approaches in the assessment of false report probability were published, the false-positive report probability (FPRP) and the Bayesian false-discovery probability (BFDP).^{12,13} FPRP and BFDP have been used in various genetic studies and field synopses in cancer studies (i.e., lung, ovarian, colorectal, gastric, hematologic) to identify genuine noteworthy genetic variants.^{5,14-21} However, attempts to discover noteworthy variants in autoimmune diseases using FPRP and BFDP are scarce.

1. False-positive report probability

FPRP is defined as “the probability of no true association between a gene variant and disease (null hypothesis)” for a statistically significant finding now assumed as a $P < 0.05$.¹¹ Developed by Wacholder et al.,¹² FPRP is calculated with the observed P value, statistical power of the test, and the prior probability that an association is true. The prior probabilities we assumed when calculating FPRP were 10^{-3} for a candidate gene variant and 10^{-6} for a random single nucleotide polymorphism (SNP) as suggested by Wacholder et al.¹² In our previous field synopsis of SLE,⁴ we calculated FPRP at those 2 assumed prior probabilities. The statistical power to detect an odds ratio (OR) of 1.2 and 1.5 was used for FPRP at both prior probabilities. Statistical power based on the ability to detect an OR of 1.5 (or its reciprocal $1/1.5 = 0.67$ for an $OR < 1$) was first proposed by Wacholder et al.,¹² which we thought might be too conservative. Thus, we advocate using statistical power to detect an OR of the median among the results of studies and 1.5. The FPRP can be obtained using the following equation:

$$FPRP = \frac{\alpha(1-\pi)}{\alpha(1-\pi) + (1-\beta)\pi} \quad (1)$$

where π is the prior probability, α is the lowest level of significance at which a test is noteworthy ($\alpha = 0.05$), while $(1-\beta)$ is the statistical power obtained using the following equation:

$$1-\beta = \phi \left(\frac{[\log(OR_A/OR_O)]}{\sigma} - Z_{\alpha/2} \right) \quad (2)$$

where ϕ is the cumulative distribution function of the standard normal distribution and $Z_{\alpha/2}$ is the $\alpha/2$ point of the standard cumulative normal distribution. For the actual computation of

FPRP, σ and $Z_{\alpha/2}$ are replaced by the standard error of the log-OR estimates and the 2-sided P value point of the standard normal distribution. All FPRP computations were performed using the Excel spreadsheet provided by Wacholder et al.,¹² and associations with $FPRP < 0.2$ were considered noteworthy as recommended by the authors.

2. Bayesian false-discovery probability

BFDP values can be obtained using methods created by Wakefield.¹³ This provides information based on the cost of a false discovery and a false nondiscovery. Different from FPRP, BFDP is calculated using the following equation:

$$BFDP = \frac{ABF \times PO}{ABF \times PO + 1} \quad (3)$$

where PO is the prior odds of the null hypothesis and is equal to $\pi_0/(1-\pi_0)$ wherein π_0 is the prior probability of the null hypothesis and ABF is the approximate Bayesian factor computed using OR and standard error. Its approximation is based on a logistic regression model instead of a standard normal distribution. The noteworthiness is assessed with the cutoff value of 0.8 for BFDP, which means a false nondiscovery 4 times as costly as a false discovery.¹³

BFDP seems more reasonable with sound methodological derivation than FPRP. While FPRP is stated as the lowest FPRP value at which a test would yield a noteworthy finding and assumes a specific point as a prior,¹² BFDP uses average over all alternatives as a prior.¹³ In other words, FPRP produces posterior null estimates that are smaller than those produced by BFDP because FPRP is essentially the lower bound on the posterior probability corresponding to the observed estimates.²² All BFDP computations were performed using the Excel spreadsheet provided by Wakefield (<http://faculty.washington.edu/jonno/cv.html>).¹³

3. Tendencies of FPRP and BFDP with P values

The main purpose of the methods we introduced in this review is to discover false-positive results, which already satisfy the current scientific statistical standards regarding a P value indicating statistical significance. Therefore, with the published results of the SLE field synopsis and systematic review,⁴ we calculated the proportion of noteworthy variants relevant to the P value. A conventional meta-analysis of observational studies defines its significance with a P value of less than 0.05, whereas a meta-analysis of GWAS uses 5×10^{-8} as a threshold. We excluded data with which the results of FPRP or BFDP were not mathematically calculable, expressed as “NA.”

The ratio for the noteworthy variants out of positive findings in the meta-analysis of observational studies decreased stiffly as the P value exceeded 0.001 for both FPRP and BFDP (Fig. 1). In the same manner, the ratio of the noteworthy findings among the meta-analysis results of GWAS by FPRP computation decreased to 0.5 with a P value $> 10^{-5}$ (Fig. 2), while BFDP also showed a sudden decrease in the number of noteworthy variants at a

$P \geq 10^{-5}$. The difference between FPRP and BFDP is that more genetic variants located in the borderline ($5 \times 10^{-8} < P < 0.05$) significance in GWAS meta-analyses were noteworthy in BFDP than in FPRP (Fig. 2).

The current cutoff for a $P < 0.05$ might be too broad, as it would yield too many false-positive results, thus leading to the overinterpretation of the retrieved results. According to the findings of this review, the statistical significance in the meta-analysis of observational studies requires evaluation with a more stringent P value. Furthermore, GWAS meta-analysis results are highly reliable because all variants under a P value of 5×10^{-8} were noteworthy with FPRP and BFDP computations (Table 1).

Noteworthy genetic variants in SLE and their functions

Our previous systematic review of SLE calculated noteworthy of published significant genetic variants using FPRP and BFDP.⁴ Table 1 summarizes the proportion of noteworthy gene variants in each type of GWAS according to the different statistical approaches and significance thresholds. Seventy-five

distinct genes with 133 genotype comparisons from observational studies were identified as significant. Of the 133 genotype comparisons, 23 (17%) and 11 (8%) were verified as noteworthy (< 0.2) using FPRP estimation at a prior probability of 10^{-3} and 10^{-6} with statistical power to detect an OR of 1.2. In addition, 34 (26%) and 18 (14%) showed a noteworthy at a prior probability of 10^{-3} and 10^{-6} with a statistical power to detect an OR of 1.5. In terms of BFDP, 50 (38%) and 29 (22%) comparisons had noteworthy findings (< 0.8) at a prior probability of 10^{-3} and 10^{-6} . Seventy genes with 89 genotype comparisons extracted from GWAS were reportedly significant with a $P < 5 \times 10^{-8}$. On FPRP, 64 comparisons were noteworthy (< 0.2) at both prior probabilities of 10^{-3} and 10^{-6} with a statistical power to detect an OR of 1.2 and 1.5. The noteworthy of 25 comparisons was not available for the same reason as mentioned above. With respect to BFDP estimations, all of the calculated values at both prior probabilities of 10^{-3} and 10^{-6} were < 0.8 , indicating noteworthy. As a result, all of the statistically significant results of the meta-analyses of GWAS were assessed to be definitely noteworthy under FPRP and BFDP. A total of 25 genes with 27 genotype comparisons were organized, which had a borderline statistical significance (P value of 0.05 to

Fig. 1. The ratio of noteworthy findings over statistically significant findings by FPRP and BFDP in the meta-analysis of observational studies. The y-axis is the ratio of noteworthy variants by FPRP (A): 0.76, 0.95, 0.5, 0.04 from left to right; and by BFDP (B): 0.89, 0.6, 0.48, 0.02. The x-axis is the range of P values. BFDP, Bayesian false-discovery probability; FPRP, false-positive report probability.

Fig. 2. The ratio of noteworthy findings by FPRP and BFDP in the meta-analysis of genome-wide association studies. The y-axis is the ratio of noteworthy findings over statistically significant findings by FPRP (A): 1.0, 0.38, 0.29, 0.2; and by BFDP (B): 1.0, 0.5, 0.29, 0.4. BFDP, Bayesian false-discovery probability; FPRP, false-positive report probability.

Table 1. Proportion of noteworthy gene variants by statistical approach and significance threshold

| Meta-analyses | No. of SNP studies | <i>P</i> <0.05 | FPRP values at prior probability | | | | BFDP 0.001 | BFDP 0.000001 |
|---|--------------------|----------------|----------------------------------|----------|----------|----------|------------|---------------|
| | | | OR 1.2 | | OR 1.5 | | | |
| | | | 0.001 | 0.000001 | 0.001 | 0.000001 | | |
| Observational studies | 133 | 133 (100) | 23 (17) | 11 (8) | 34 (26) | 18 (14) | 50 (38) | 29 (22) |
| GWAS (<i>P</i> <5×10 ⁻⁸) ^{a)} | 89 | 89 (100) | 64 (100) | 64 (100) | 64 (100) | 64 (100) | 89 (100) | 89 (100) |
| GWAS (5×10 ⁻⁸ < <i>P</i> <0.05) | 27 | 27 (100) | 13 (48) | 2 (7) | 13 (48) | 2 (7) | 15 (56) | 1 (4) |

Values are presented as number (%).

SNP, single nucleotide polymorphism; FPRP, false-positive report probability; OR, odds ratio; BFDP, Bayesian false-discovery probability; GWAS, genome-wide association studies.

^{a)}The noteworthiness of 25 comparisons was not available for FPRP among 89 genotype comparisons extracted from meta-analyses of GWAS with a *P*<5×10⁻⁸.

5×10⁻⁸). Under FPRP estimation, 13 (48%) and 2 (7%) were assessed to be noteworthy at a prior probability of 10⁻³ and 10⁻⁶ with a statistical power to detect an OR of 1.2. Moreover, 13 (48%) and 2 (7%) were identified as noteworthy at a prior probability of 10⁻³ and 10⁻⁶ with a statistical power to detect an OR of 1.5. In terms of BFDP, 15 (56%) and 1 (4%) comparisons were found noteworthy at a prior probability of 10⁻³ and 10⁻⁶.

We found that the GWAS meta-analysis results were highly reliable because all variants under a *P* value of 5×10⁻⁸ were evaluated as noteworthy with FPRP and BFDP computations. The GWAS results with *P*<5×10⁻⁸ could be identically replicated in observational studies. In addition, of the 27 genotype comparisons that had borderline statistical significance, 13 (48%) were noteworthy under both Bayesian methods, suggesting that results with a *P* value of 0.05 to 5×10⁻⁸ may be genuine associations. To verify the results obtained from genetic analyses, both Bayesian approaches may have advantages, especially for the interpretation of results obtained from observational studies. When determining the results of GWAS with *P* values ranging between 0.05 and 5×10⁻⁸, statistical approaches other than single standard significance may be beneficial, and we were able to confirm significance in almost half of the genetic variants within this borderline significance range. Therefore, it is attractive to speculate that genetic variants with borderline significance require further analysis for a genuine association.⁴⁾

Noteworthy genetic variants in SLE and their functions are summarized in Table 2. Investigation of the sorted list of significant genes identified a prominent representation of genes that have a role in interferon (IFN) signaling, which was in line with previous reports.^{23,24)} These genes were *IFIH1*, *IRF5*, *IRF8*, and *STAT4* from the observational studies and *IFIH1*, *IRF5*, *IRF7*, *IRF8*, *PRDM1-ATG5*, *STAT4*, and *TYK2* from GWAS. IFN-α, a type I IFN, is traditionally known to be concerned with a defense against viruses and its involvement in breaking self-tolerance via the activation of antigen-presenting cells after absorbing self-materials,²⁵⁾ which explains some essential parts of the current understanding of SLE.²⁶⁾ In addition, the proportion of genes whose function is related to nuclear factor kappa B (NF-κB) signaling was also outstanding. NF-κB plays a critical role in proinflammatory processes through regulating the expression of tumor necrosis factor-α (TNF-α), toll-like receptors, and inter-

leukin 1 receptor.²⁷⁾ These were *MECP2* and *TNFAIP3* from observational studies and *IKBKE*, *IRAK1*, *MECP2*, *SLC15A4*, *TNFAIP3*, *TNIP1*, and *UBE2L3* from GWAS. Other genes with relevance to the immune system such as complement activation, apoptosis, and neutrophil, monocyte, NK cell, and B- and T-cell signaling were significantly related to the genetic susceptibility loci for SLE.²⁸⁾

Gene network analysis

As the bioinformatic open resources are overwhelming, we thought that using noteworthy genetic variants for gene network analyses with open source methods should derive a genuine etiopathology of the respective disease. Several databases have compiled data from experimental and computational sources, integrating extensive protein-protein interactions (PPIs) or gene-gene interactions. STRING (Search Tool for the Retrieval of Interacting Genes/Proteins) and GeneMANIA are representative freely available databases that were constructed from various biological and literature sources. The utilization of these interactions among genes aids the understanding of the underlying biological mechanisms as well as the hidden pathology of human disease associated with the genes.²⁹⁾ Since different databases are constructed based on different biological evidence, the utilization of the appropriate network database is very critical for identifying meaningful interaction information. A recent interesting benchmarking study comparing the performance of different network databases in the context of virus-host interactions and STRING databases revealed overall good performance for detecting known host factors for various human genes.³⁰⁾ In this review, we introduced the process of sorting out noteworthy variants from the known statistically significant variants; furthermore, we applied the 2 representative databases STRING and GeneMANIA and genetic variants associated with SLE in our previous field synopsis⁴⁾ to the STRING database to construct a PPI network.

1. GeneMANIA

The GeneMANIA database³¹⁾ includes 1,800 networks covering 500 million gene-gene interactions and PPI from 9 organisms

Table 2. Noteworthy genetic variants and their functions

| Study | Gene | Variant (RS number) | Ethnicity, study No. (types of study) | Comparison | OR (95% CI) | P value | Function of genes |
|--------------------------------------|------------------|---------------------|---------------------------------------|--------------|---------------------|------------------------|---|

Table 2. Noteworthy genetic variants and their functions (Continued)

| Study | Gene | Variant (RS number) | Ethnicity, study No. (types of study) | Comparison | OR (95% CI) | P value | Function of genes |
|------------------------------------|---------------------|---------------------|---------------------------------------|--------------|---------------------|-------------------------|--|
| Bentham et al. 2015 ³⁵⁾ | <i>CFB</i> | rs1270942 | European 2 (MG) | G<A | 2.28 (2.15-2.42) | 2.25×10 ⁻¹⁶⁵ | <i>CFB</i> gene encodes complement factor B, a component of the alternative pathway of complement activation. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>CIITA-SOCS1</i> | rs9652601 | European 2 (MG) | A<G | 1.21 (1.15-1.26) | 7.42×10 ⁻¹⁷ | <i>CIITA</i> gene encodes a protein with an acidic transcriptional activation domain, 4 LRRs (leucine-rich repeats) and a guanosine triphosphate binding domain. The protein acts as a positive regulator of class II major histocompatibility complex gene transcription. ³⁸⁾ <i>SOCS1</i> gene encodes a member of the signal transducer and activator of transcription (STAT)-induced STAT inhibitor (SSI) family, also known as suppressor of cytokine signaling. It takes part in a negative feedback loop to attenuate cytokine signaling. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>CSK</i> | rs2289583 | European 2 (MG) | A<C | 1.19 (1.14-1.24) | 6.22×10 ⁻¹⁵ | The protein encoded by the <i>CSK</i> gene is involved in multiple pathways, including the regulation of Src family kinases. It plays an important role in T-cell activation through its association with the protein encoded by the protein tyrosine phosphatase, nonreceptor type 22 (<i>PTPN22</i>) gene. An intronic polymorphism (rs34933034) in this gene has been found to affect B-cell activation and is associated with SLE. ³⁸⁾ |
| Shojaa et al. 2014 ⁵¹⁾ | <i>CTLA-4</i> | rs733618 | Overall 8 (MO) | TT vs. CC | 2.32 (1.62-3.32) | <0.001 | <i>CTLA-4</i> gene is a member of the immunoglobulin superfamily and encodes a protein which transmits an inhibitory signal to T cells. ³⁸⁾ |
| Zhang et al. 2014 ⁵²⁾ | <i>CXCR5</i> | rs10892301 | Asian 3 (MG) | A<G | 0.85 (0.80-0.90) | 2.51×10 ⁻⁸ | <i>CXCR5</i> gene encodes a multipass membrane protein that belongs to the CXC chemokine receptor family. This cytokine receptor is involved in B-cell migration into B-cell follicles of spleen and Peyer patches. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>Cxorf21</i> | rs887369 | European 2 (MG) | A<C | 1.15 (1.10-1.21) | 5.26×10 ⁻¹⁰ | A protein coding gene of unknown function. ⁵³⁾ |
| Lessard et al. 2016 ³⁹⁾ | <i>DOCK1</i> | rs10901656 | Asian 2 (MG) | T<C | 1.21 (1.12-1.32) | 9.56×10 ⁻⁶ | <i>DOCK1</i> gene encodes a member of the dedicator of cytokinesis protein family. Dedicator of cytokinesis proteins regulates the small GTPase Rac, thereby influencing several biological processes, including phagocytosis and cell migration. ³⁸⁾ |
| Wang et al. 2013 ⁵⁴⁾ | <i>ETS1</i> | rs6590330 | Caucasian 3 (MG) | A<G | 1.22 (1.10-1.34) | 9.8×10 ⁻⁵ | <i>ETS1</i> gene encodes for a transcription factor known to be involved in a wide range of immune functions, including Th17 cell development and terminal differentiation of B lymphocytes. ⁵⁵⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>ETS1-FLI1</i> | rs7941765 | European 2 (MG) | T<C | 1.14 (1.10-1.19) | 1.35×10 ⁻¹⁰ | <i>FLI1</i> gene encodes a transcription factor containing an ETS DNA-binding domain. ³⁸⁾ |
| Lee et al. 2012 ⁴⁷⁾ | <i>FAM167A</i> | rs12680762 | European 2 (MG) | A<G | 1.335 (1.208-1.475) | 1.45×10 ⁻⁸ | <i>FAM167A</i> gene is a ubiquitously expressed gene of unknown function. |
| Bentham et al. 2015 ³⁵⁾ | <i>FCGR2A</i> | rs1801274 | European 2 (MG) | C<T | 1.16 (1.11-1.21) | 1.04×10 ⁻¹² | <i>FCGR2A</i> gene encodes a cell-surface receptor found on phagocytic cells such as macrophages and neutrophils, and is involved in the process of phagocytosis and clearing of immune complexes. ³⁸⁾ |
| Zhu et al. 2016 ⁵⁶⁾ | <i>FCGR2B</i> | rs1050501 | Overall 12 (MO) | CC vs. CT+TT | 1.754 (1.422-2.165) | 1.61×10 ⁻⁷ | <i>FCGR2B</i> is an immunoreceptor tyrosine-based inhibitory motif (ITIM)-containing receptor and it mediates both endocytotic and apoptotic signaling on B cells and myelomonocytic cells. |
| Zhu et al. 2016 ⁵⁶⁾ | <i>FCGR3A</i> | rs396991 | Overall 26 (MO) | TT vs. TG+GG | 1.263 (1.123-1.421) | 9.62×10 ⁻⁵ | <i>FCGR3A</i> gene is involved in the removal of antigen-antibody complexes from the circulation, as well as other antibody-dependent responses. The encoded receptor is expressed on natural killer (NK) cells. ³⁸⁾ |
| Lessard et al. 2016 ³⁹⁾ | <i>FCHSD2-P2RY2</i> | rs11235667 | Asian 2 (MG) | G<A | 0.63 (0.55-0.72) | 6.67×10 ⁻¹¹ | <i>FCHSD2</i> gene has been described as regulator of F-actin assembly through interactions with WAS (also known as WASP) and WASL (also known as N-WASP). WAS plays an important role in the migration of T cells through reorganization of the actin cytoskeleton subsequent to interactions with dendritic or B cells. P2RY2 is a receptor for adenosine triphosphate (ATP) and uridine triphosphate (UTP) that acts as a sensor for the release of nucleotides by apoptotic cells. It is also known to induce CCL2 secretion in macrophages. |
| Sheng et al. 2015 ⁵⁰⁾ | <i>FLJ25996</i> | rs9866504 | Chinese 3 (MG) | G<A | 0.85 (0.79-0.92) | 6.44×10 ⁻² | No information |
| Sheng et al. 2015 ⁵⁰⁾ | <i>GPM6A</i> | rs997779 | Chinese 3 (MG) | G<A | 1.17 (1.08-1.26) | 4.48×10 ⁻² | <i>GPM6A</i> gene is abundant in all rat hippocampal subregions, and it localized to membrane protrusions (filopodia/spines) of primary hippocampal neurons. This gene has a role in neurite/filopodium outgrowth and synapse formation. |
| Lessard et al. 2016 ³⁹⁾ | <i>GTF2IRD1</i> | rs2267828 | Asian 2 (MG) | G<A | 0.81 (0.76-0.88) | 6.46×10 ⁻⁸ | The protein encoded by this gene contains 5 GTF2I-like repeats and each repeat possesses a potential helix-loop-helix (HLH) motif. It may interact with other HLH-proteins and function as a transcription factor or as a positive transcriptional regulator under the control of Retinoblastoma protein. This gene plays a role in craniofacial and cognitive development. ³⁸⁾ |

Table 2. Noteworthy genetic variants and their functions (Continued)

| Study | Gene | Variant (RS number) | Ethnicity, study No. (types of study) | Comparison | OR (95% CI) | P value | Function of genes |
|--|--------------------------|---------------------|---------------------------------------|--------------|---------------------|------------------------|--|
| Morris et al. 2016 ⁴²⁾ | <i>GTF2IRD1-GTF2I</i> | rs73135369 | Overall 3 (MG) | C<T | 1.32 (1.23-1.42) | 8.77×10 ⁻¹⁴ | This gene encodes a phosphoprotein containing 6 characteristic repeat motifs. The encoded protein binds to the initiator element (Inr) and E-box element in promoters and functions as a regulator of transcription. ³⁸⁾ |
| Zhang et al. 2015 ⁵⁷⁾ | <i>HCFC1</i> | rs17422 | Asian 2 (MG) | T<C | 0.75 (0.71-0.80) | 1.47×10 ⁻¹⁵ | This gene is a member of the host cell factor family and encodes a protein with 5 Kelch repeats, a fibronectin-like motif, and 6 HCF repeats, each of which contains a highly specific cleavage signal. It is involved in control of the cell cycle and transcriptional regulation during herpes simplex virus infection. ³⁸⁾ |
| Niu et al. 2015 ⁵⁸⁾ | <i>HLA-DR3</i> | | Overall 17 (MO) | DR3 | 1.88 (1.58-2.23) | <0.001 | Major histocompatibility complex, class II, DR beta 1 (HLA-DRB1 gene). The HLA-DRB1 locus is ubiquitous and encodes a very large number of functionally variable gene products (HLA-DR1 to HLA-DR17). HLA-DRB1 belongs to the HLA class II beta chain paralogs. It plays a central role in the immune system by presenting peptides derived from extracellular proteins. Class II molecules are expressed in antigen-presenting cells (APC: B lymphocytes, DCs, macrophages). ³⁸⁾ |
| Niu et al. 2015 ⁵⁸⁾ | <i>HLA-DR11</i> | | Overall 15 (MO) | DR11 | 0.72 (0.60-0.85) | <0.0001 | |
| Castaño-Rodríguez et al. 2008 ⁵⁹⁾ | <i>HLA-DR2</i> | | Latin American 9 (MO) | DR2 | 1.754 (1.404-2.191) | 0 | |
| Lee et al. 2015 ⁶⁰⁾ | <i>HLA-G</i> | rs1063320 | Overall 4 (MO) | G vs. C | 1.367 (1.158-1.613) | 2.2×10 ⁻⁵ | HLA-G belongs to the HLA class I heavy chain paralogs. ³⁸⁾ Nonclassic HLA-G class I molecules inhibit natural killer cell function. ⁶¹⁾ |
| Kim et al. 2012 ⁶²⁾ | <i>ICAM1-ICAM4-ICAM5</i> | rs3093030 | Overall 4 (MO) | A vs. G | 1.16 (1.11-1.22) | 4.88×10 ⁻¹⁰ | <i>ICAM1</i> gene encodes a cell-surface glycoprotein which is mainly expressed in the vascular endothelium, macrophages and lymphocytes, and plays a role in immunological events including extravasation and T-cell-mediated responses. <i>ICAM4</i> gene encodes the Landsteiner-Wiener blood group antigen(s) that belongs to the immunoglobulin (Ig) superfamily. It contains 2 Ig-like C2-type domains and binds to the leukocyte adhesion LFA-1 protein. <i>ICAM5</i> is preferentially expressed in brain. |
| Bentham et al. 2015 ³⁵⁾ | <i>IFIH1</i> | rs2111485 | European 2 (MG) | C<G | 1.15 (1.11-1.20) | 1.27×10 ⁻¹¹ | <i>IFIH1</i> gene encodes a DEAD box protein that is upregulated in response to treatment with beta-interferon and a protein kinase C-activating compound, mezerein. The encoded protein participates in the activation of apoptosis in viral dsRNA infected cells, modulating type 1 interferon (IFN) response, production of proinflammatory cytokines and apoptotic processes. ⁶³⁾ |
| Morris et al. 2016 ⁴²⁾ | <i>IKBKE</i> | rs2297550 | Overall 3 (MG) | G<C | 1.16 (1.11-1.21) | 1.31×10 ⁻¹¹ | IKBKE is a noncanonical I-kappa-B kinase that is essential for regulating antiviral signaling pathways. |
| Bentham et al. 2015 ³⁵⁾ | <i>IKZF1</i> | rs4917014 | European 2 (MG) | G<T | 1.18 (1.13-1.24) | 6.39×10 ⁻¹⁴ | <i>IKZF1</i> gene encodes a transcription factor associated with chromatin remodeling. It functions as a regulator of lymphocyte differentiation. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>IKZF2</i> | rs3768792 | European 2 (MG) | G<A | 1.24 (1.17-1.31) | 1.21×10 ⁻¹³ | <i>IKZF2</i> gene encodes a member of the Ikaros family of zinc-finger proteins that is involved in the regulation of lymphocyte development. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>IKZF3</i> | rs2941509 | European 2 (MG) | T<C | 1.35 (1.22-1.49) | 7.98×10 ⁻⁹ | <i>IKZF3</i> gene encodes a member of the Ikaros family of zinc-finger proteins. This gene product is a transcription factor that is important in the regulation of B-lymphocyte proliferation and differentiation. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>IL-10</i> | rs3024505 | European 2 (MG) | A<G | 1.17 (1.11-1.24) | 4.64×10 ⁻⁹ | Interleukin (IL)-10 is produced primarily by monocytes and to a lesser extent by lymphocytes. It down-regulates the expression of Th1 cytokines, major histocompatibility complex (MHC) class II Ags, and costimulatory molecules on macrophages. It enhances B-cell survival, proliferation, and antibody production. It can block NF-kappa B activity, and is involved in the regulation of the Janus kinase (JAK)-STAT signaling pathway. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>IL-12A</i> | rs564799 | European 2 (MG) | C<T | 1.14 (1.09-1.18) | 1.54×10 ⁻⁹ | IL-12A acts on T and natural killer cells. It is required for the T-cell-independent induction of IFN-gamma, and is important for the differentiation of both Th1 and Th2 cells. ³⁸⁾ |
| Qi et al. 2015 ⁶⁴⁾ | <i>IL-21</i> | rs907715 | Overall 7 (MO) | GG+GA vs. AA | 1.20 (1.09-1.31) | 0 | IL-21 plays a role in both the innate and adaptive immune responses by inducing the differentiation, proliferation and activity of multiple target cells including macrophages, natural killer cells, B cells and cytotoxic T cells. ³⁸⁾ |
| Webb et al. 2009 ⁶⁵⁾ | <i>IL-21R</i> | rs3093301 | Overall 2 (MO) | A vs. G | 1.16 (1.08-1.25) | 1.0×10 ⁻⁴ | <i>IL-21R</i> gene encodes a cytokine receptor for IL-21. It transduces the growth promoting signal of IL21, and is important for the proliferation and differentiation of T cells, B cells, and NK cells. ³⁸⁾ |

Table 2. Noteworthy genetic variants and their functions (Continued)

| Study | Gene | Variant (RS number) | Ethnicity, study No. (types of study) | Comparison | OR (95% CI) | P value | Function of genes |
|--------------------------------------|----------------------|---------------------|---------------------------------------|------------|---------------------|-------------------------|---|
| Katkam et al. 2017 ⁶⁶⁾ | <i>IL-6</i> | rs1800797 | Overall 13 (MO) | G vs. C | 1.36 (1.22-1.53) | 0.00 | <i>IL-6</i> functions in inflammation and the maturation of B cells. In addition, it has been shown to be an endogenous pyrogen capable of inducing fever in people with autoimmune diseases or infections. ³⁸⁾ |
| Zhang et al. 2015 ⁵⁷⁾ | <i>IRAK1</i> | rs1059702 | Asian 2 (MG) | C<T | 0.71 (0.67-0.76) | 2.40×10 ⁻¹⁸ | <i>IRAK1</i> gene encodes the interleukin-1 receptor-associated kinase 1. It is partially responsible for IL-1-induced upregulation of the transcription factor NF-kappa B. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>IRF5</i> | rs10488631 | European 2 (MG) | C<T | 1.92 (1.81-2.03) | 9.37×10 ⁻¹¹⁰ | Proteins of the interferon regulatory factor (IRF) family bind to the IFN-stimulated response element and regulate expression of genes stimulated by type I IFNs, namely IFN-alpha and IFN-beta. IRF family proteins also control expression of IFN-alpha and IFN-beta-regulated genes that are induced by viral infection. ³⁸⁾ |
| Lee et al. 2012 ⁴⁷⁾ | <i>IRF5</i> | rs729302 | European 2 (MG) | C<A | 0.774 (0.707-0.848) | 3.93×10 ⁻⁸ | |
| Bentham et al. 2015 ³⁵⁾ | <i>IRF7</i> | rs12802200 | European 2 (MG) | A<C | 1.23 (1.15-1.31) | 8.81×10 ⁻¹⁰ | |
| Bentham et al. 2015 ³⁵⁾ | <i>IRF8</i> | rs11644034 | European 2 (MG) | A<G | 1.25 (1.19-1.32) | 9.58×10 ⁻¹⁸ | |
| Sheng et al. 2015 ⁵⁰⁾ | <i>IRF8</i> | rs2934498 | Chinese 2 (MG) | G<A | 1.25 (1.16-1.34) | 4.97×10 ⁻⁹ | |
| Bentham et al. 2015 ³⁵⁾ | <i>ITGAM</i> | rs34572943 | European 2 (MG) | A<G | 1.71 (1.61-1.81) | 3.39×10 ⁻⁷⁶ | <i>ITGAM</i> gene encodes the integrin alpha M chain. It is important in the adherence of neutrophils and monocytes to stimulated endothelium, and also in the phagocytosis of complement coated particles. ³⁸⁾ |
| Morris et al. 2016 ⁴²⁾ | <i>JAK2</i> | rs1887428 | Overall 3 (MG) | G<C | 1.16 (1.12-1.20) | 2.19×10 ⁻¹⁷ | <i>JAK2</i> encodes a tyrosine kinase involved in a specific subset of cytokine receptor signaling pathways. It has been found to be associated with the prolactin receptor and is required for responses to gamma interferon. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>JAZF1</i> | rs849142 | European 2 (MG) | C<T | 1.14 (1.10-1.19) | 8.61×10 ⁻¹¹ | <i>JAZF1</i> gene encodes a nuclear protein that functions as a transcriptional repressor. ³⁸⁾ |
| Zhang et al. 2015 ⁵⁷⁾ | <i>L1CAM</i> | rs4898457 | Asian 2 (MG) | G<A | 0.87 (0.82-0.92) | 2.84×10 ⁻⁶ | <i>L1CAM</i> gene encodes an axonal glycoprotein belonging to the immunoglobulin supergene family. This cell adhesion molecule plays an important role in nervous system development, including neuronal migration and differentiation. ³⁸⁾ |
| Morris et al. 2016 ⁴²⁾ | <i>LBH</i> | rs17321999 | Overall 3 (MG) | A<C | 0.83 (0.79-0.87) | 2.22×10 ⁻¹⁶ | <i>LBH</i> (limb bud and heart development) is a key gene regulator which could act as a transcriptional coactivator in the mitogen-activated protein kinase signaling pathway to mediate cellular functions. Several SNP within <i>LBH</i> are associated with rheumatoid arthritis and SLE. ⁶⁷⁾ |
| Morris et al. 2016 ⁴²⁾ | <i>LBH</i> | rs7579944 | Overall 3 (MG) | C<T | 0.90 (0.87-0.93) | 1.41×10 ⁻⁹ | |
| Morris et al. 2016 ⁴²⁾ | <i>LPP-TPRG1-AS1</i> | rs6762714 | Overall 3 (MG) | C<T | 1.16 (1.12-1.20) | 4.00×10 ⁻¹⁵ | <i>LPP</i> gene encodes a protein localizes to the cell periphery in focal adhesions and may be involved in cell-cell adhesion and cell motility. It also functions as a transcriptional coactivator. ³⁸⁾ |
| Wang et al. 2013 ⁵⁴⁾ | <i>LRRC18-WDFY4A</i> | rs1913517 | Caucasian 3 (MG) | A<G | 1.16 (1.08-1.23) | 7.8×10 ⁻⁶ | Both <i>LRRC18</i> and <i>WDFY4</i> are of unknown function. |
| Bentham et al. 2015 ³⁵⁾ | <i>LYST</i> | rs9782955 | European 2 (GWAS) | T<C | 1.16 (1.11-1.22) | 1.25×10 ⁻⁹ | <i>LYST</i> gene encodes a protein that regulates intracellular protein trafficking in endosomes, and may be involved in pigmentation. ³⁸⁾ No known immune function. Studies have revealed that <i>LYST</i> functions in lysosomal trafficking in many immune cells, a process that is also crucial in the activation of TLRs by self-nucleic acids in SLE. ⁶⁸⁾ |
| Lee et al. 2012 ⁵⁹⁾ | <i>MBL2</i> | rs1800450 | Overall 21 (MO) | B vs. A | 1.298 (1.154-1.459) | 1.49×10 ⁻⁵ | <i>MBL2</i> gene encodes the soluble mannose-binding lectin or protein. It recognizes mannose and N-acetylglucosamine on many microorganisms, and is capable of activating the classical complement pathway. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>MECP2</i> | rs1734787 | European 2 (MG) | C<A | 1.31 (1.22-1.40) | 1.78×10 ⁻¹⁵ | <i>MECP2</i> is a dichotomous transcriptional regulator that either activates or represses gene expression. ⁷⁰⁾ |
| Zhang et al. 2015 ⁵⁷⁾ | <i>MECP2</i> | rs2734647 | Asian 2 (MG) | C<T | 0.72 (0.67-0.76) | 5.22×10 ⁻¹⁸ | |
| Bentham et al. 2015 ³⁵⁾ | <i>miR-146a</i> | rs2431697 | European 2 (MG) | C<T | 1.26 (1.21-1.31) | 8.01×10 ⁻²⁸ | MicroRNA 146a can repress type 1 IFN pathway through targeting TNF receptor-associated factor 6, IL-1 receptor-associated kinase, IFN regulator factor 5 (IRF5), and STAT-1. ⁷¹⁾ |
| Molineros et al. 2017 ⁴¹⁾ | <i>MYNN</i> | rs10936599 | Overall 9 (MG) | C<T | 1.14 (1.10-1.18) | 1.92×10 ⁻¹³ | <i>MYNN</i> encodes the zinc-finger transcription factor myoneurin, which regulates neuromuscular junctions and telomere length. ⁴¹⁾ |
| Zhang et al. 2015 ⁵⁷⁾ | <i>NAA10</i> | rs1557501 | Asian 2 (MG) | C<T | 0.83 (0.79-0.88) | 7.84×10 ⁻¹⁰ | <i>NAA10</i> gene encodes an N-terminal acetyltransferase that functions as the catalytic subunit of the major amino-terminal acetyltransferase A complex. ³⁸⁾ |
| Zhang et al. 2015 ⁵⁷⁾ | <i>NAA10</i> | rs2071128 | Asian 2 (MG) | G<A | 0.81 (0.77-0.86) | 2.19×10 ⁻¹³ | |

Table 2. Noteworthy genetic variants and their functions (Continued)

| Study | Gene | Variant (RS number) | Ethnicity, study No. (types of study) | Comparison | OR (95% CI) | P value | Function of genes |
|---------------------------------------|-------------------|---------------------|---------------------------------------|------------|---------------------|------------------------|---|
| Bentham et al. 2015 ³⁵⁾ | <i>NADSYN1</i> | rs3794060 | European 2 (MG) | T<C | 1.23 (1.18-1.29) | 1.32×10 ⁻²⁰ | This gene encodes a synthetase that catalyzes the final step in the biosynthesis of Nicotinamide adenine dinucleotide. |
| Zhang et al. 2015 ⁵⁷⁾ | <i>Near-VCX2</i> | rs5978830 | Asian 2 (MG) | A<G | 0.84 (0.80-0.89) | 1.00×10 ⁻⁸ | This gene belongs to the <i>VCX/Y</i> gene family, which has multiple members on both X and Y chromosomes that are expressed exclusively in male germ cells. The <i>VCX</i> gene cluster is polymorphic in terms of copy number; different individuals may have a different number of <i>VCX</i> genes. This gene contains 2 copies of a 30 nt tandem repeat. Deletion of a nearby member of this family was implicated in cognitive disability. ³⁸⁾ |
| Sheng et al. 2015 ⁵⁰⁾ | <i>NRXN1</i> | rs2048979 | Chinese 3 (MG) | G/A | 0.87 (0.82-0.91) | 1.35×10 ⁻³ | Neurexins are cell-surface receptors that bind neuroligins to form Ca(2+)-dependent neurexin/neuroligin complexes at synapses in the central nervous system. This complex is required for efficient neurotransmission and is involved in the formation of synaptic contacts. ³⁸⁾ |
| Lee et al. 2017 ⁷²⁾ | <i>OPN</i> | rs11229919 | Asian 2 (MO) | C vs. T | 2.070 (1.570-2.730) | 2.5×10 ⁻⁷ | The protein encoded by this gene is involved in the attachment of osteoclasts to the mineralized bone matrix. It is also a cytokine that upregulates expression of interferon-gamma and interleukin-12. ³⁸⁾ |
| Zhang et al. 2014 ⁵²⁾ | <i>PHLDB1</i> | rs11603023 | Asian 3 (MG) | T<C | 1.20 (1.12-1.27) | 1.25×10 ⁻⁸ | PHLDB1 is an insulin responsive protein that enhances AKT activation. AKT signaling pathway plays an important role in cellular proliferation and growth signaling. Abnormal activation of the AKT signaling pathway was found in peripheral blood T cells from individuals with SLE. ⁵²⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>PLD2</i> | rs2286672 | European 2 (MG) | T<C | 1.25 (1.16-1.35) | 2.93×10 ⁻⁹ | The protein encoded by this gene catalyzes the hydrolysis of phosphatidylcholine to phosphatidic acid and choline. This protein localizes to the peripheral membrane and may be involved in cytoskeletal organization, cell cycle control, transcriptional regulation, and/or regulated secretion. ³⁸⁾ |
| Tan et al. 2011 ⁷³⁾ | <i>PPP2CA</i> | rs10491322 | Overall 4 (MO) | G vs. A | 1.2 (1.07-1.27) | 3.8×10 ⁻⁴ | <i>PPP2CA</i> gene encodes the phosphatase 2A catalytic subunit. Protein phosphatase 2A is implicated in the negative control of cell growth and division. ³⁸⁾ |
| Tan et al. 2011 ⁷³⁾ | <i>PPP2CA</i> | rs7704116 | Overall 4 (MO) | A vs. G | 1.3 (1.14-1.31) | 3.8×10 ⁻⁷ | |
| Bentham et al. 2015 ³⁵⁾ | <i>PRDM1-ATG5</i> | rs6568431 | European 2 (MG) | A<C | 1.21 (1.15-1.27) | 5.04×10 ⁻¹⁴ | <i>PRDM1</i> gene encodes a protein that acts as a repressor of beta-interferon gene expression. ³⁸⁾ The encoded protein by <i>ATG5</i> gene is involved in several cellular processes, including autophagic vesicle formation, mitochondrial quality control after oxidative damage, negative regulation of the innate antiviral immune response, lymphocyte development and proliferation, MHC II antigen presentation, adipocyte differentiation, and apoptosis. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>PTPN22</i> | rs2476601 | European 2 (MG) | T<C | 1.43 (1.34-1.53) | 1.10×10 ⁻⁸ | <i>PTPN22</i> gene encodes a lymphoid-specific intracellular phosphatase that associates with the molecular adapter protein CBL and may be involved in regulating CBL function in the T-cell receptor signaling pathway. ³⁸⁾ |
| Morris et al. 2016 ⁴²⁾ | <i>PTPRC</i> | rs34889541 | Overall 3 (MG) | A<G | 0.81 (0.76-0.86) | 2.44×10 ⁻¹² | The protein encoded by this gene is a member of the protein tyrosine phosphatase (PTP) family. PTPs are known to be signaling molecules that regulate a variety of cellular processes including cell growth, differentiation, mitosis, and oncogenic transformation. PTP is also an essential regulator of T- and B-cell antigen receptor signaling. ³⁸⁾ |
| Ramos et al. 2011 ⁷⁴⁾ | <i>PXK</i> | rs6445975 | Overall 4 (MG) | G<T | 1.20 (1.13-1.27) | 5.27×10 ⁻⁹ | This gene encodes a phox (PX) domain-containing protein which may be involved in synaptic transmission and the ligand-induced internalization and degradation of epidermal growth factors. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>RAD51B</i> | rs4902562 | European 2 (MG) | A<G | 1.14 (1.09-1.19) | 6.15×10 ⁻¹⁰ | RAD51 family members are evolutionarily conserved proteins essential for DNA repair by homologous recombination. Overexpression of this gene was found to cause cell cycle G1 delay and cell apoptosis, which suggested a role of this protein in sensing DNA damage. ³⁸⁾ |
| Molinerros et al. 2017 ⁴¹⁾ | <i>RNASEH2C</i> | rs1308020 | Overall 9 (MG) | T<C | 0.84 (0.81-0.88) | 2.96×10 ⁻¹⁹ | RNASEH2C encodes subunit C of the human ribonuclease H2 enzyme complex that trims RNA-DNA duplexes. |
| Morris et al. 2016 ⁴²⁾ | <i>RNASEH2C</i> | rs494003 | Overall 3 (MG) | A<G | 1.14 (1.09-1.19) | 5.81×10 ⁻⁹ | |
| Bentham et al. 2015 ³⁵⁾ | <i>SH2B3</i> | rs10774625 | European 2 (MG) | A<G | 1.13 (1.08-1.18) | 4.09×10 ⁻⁹ | The encoded protein is a key negative regulator of cytokine signaling and plays a critical role in hematopoiesis. ³⁸⁾ Functional analysis indicated that it inhibits the activation of NFAT in stimulated T cells. ⁷⁵⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>SLC15A4</i> | rs1059312 | European 2 (MG) | G<A | 1.17 (1.12-1.21) | 1.48×10 ⁻¹³ | SLC15A4 belongs to a superfamily of proton-coupled oligopeptide transporters. ⁷⁶⁾ Kobayashi et al. ⁷⁷⁾ (2014) found that B-cell-derived Slc15a4 was crucial for Tlr7 (300365)-triggered type I interferon (e.g., IFNA) and autoantibody production in a mouse model of lupus (SLE). |

Table 2. Noteworthy genetic variants and their functions (Continued)

| Study | Gene | Variant (RS number) | Ethnicity, study No. (types of study) | Comparison | OR (95% CI) | P value | Function of genes |
|--------------------------------------|------------------|---------------------|---------------------------------------|-----------------------|---------------------|-------------------------|--|
| Bentham et al. 2015 ³⁵⁾ | <i>SMG7-NCF2</i> | rs17849501 | European 2 (MG) | T<C | 2.10 (1.95-2.26) | 3.45×10 ⁻⁸⁸ | <i>SMG7</i> gene encodes a protein that is essential for nonsense-mediated mRNA decay; a process whereby transcripts with premature termination codons are targeted for rapid degradation by a mRNA decay complex. <i>NCF2</i> gene encodes neutrophil cytosolic factor 2, the cytosolic subunit of the multiprotein nicotinamide adenine dinucleotide phosphate oxidase complex found in neutrophils. It produces a burst of superoxide which is delivered to the lumen of the neutrophil phagosome. ³⁸⁾ |
| Lee et al. 2012 ⁴⁷⁾ | <i>STAT4</i> | rs10931481 | European 2 (MG) | A<G | 1.312 (1.194-1.442) | 1.74×10 ⁻⁸ | <i>STAT4</i> encodes a member of the STAT family of transcription factors. In response to cytokines and growth factors, it acts as transcription activator. This protein is essential for mediating responses to IL12 in lymphocytes, and regulating the differentiation of T helper cells. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>STAT4</i> | rs11889341 | European 2 (MG) | T<C | 1.73 (1.65-1.81) | 5.59×10 ⁻¹²² | |
| Lee et al. 2012 ⁴⁷⁾ | <i>STAT4</i> | rs7574865 | European 2 (MG) | T<G | 1.477 (1.335-1.634) | 4.06×10 ⁻¹⁴ | |
| Bentham et al. 2015 ³⁵⁾ | <i>TCF7-SKP</i> | rs7726414 | European 2 (MG) | T<C | 1.45 (1.32-1.58) | 4.44×10 ⁻¹⁶ | <i>TCF7</i> is a T-cell-specific transcription factor that regulates the expression of CD3. plays a critical role in natural killer cell and innate lymphoid cell development. ³⁸⁾ |
| Lee et al. 2016 ⁷⁸⁾ | <i>TLR7</i> | rs3853839 | Asian 3 (MO) | allele 2 vs. allele 1 | 0.773 (0.725-0.823) | <1.0×10 ⁻⁹ | The protein encoded by this gene is a member of the Toll-like receptor family which plays a fundamental role in pathogen recognition and activation of innate immunity. ³⁸⁾ |
| Zhang et al. 2015 ⁵⁷⁾ | <i>TMEM187</i> | rs2266888 | Asian 2 (MG) | G<A | 0.76 (0.72-0.81) | 8.20×10 ⁻¹⁵ | This gene consists of 2 exons and encodes a multipass membrane protein. An alternatively spliced transcript variant encoding the same protein has been found, but its biological validity is not determined. ³⁸⁾ |
| Zhang et al. 2015 ⁵⁷⁾ | <i>TMEM187</i> | rs6571303 | Asian 2 (MG) | C<T | 0.80 (0.76-0.84) | 3.06×10 ⁻¹³ | |
| Sheng et al. 2015 ⁵⁰⁾ | <i>TMEM39A</i> | rs12494314 | Chinese 3 (MG) | C<T | 0.84 (0.80-0.89) | 1.01×10 ⁻⁹ | The <i>TMEM39A</i> -associated coding SNP (rs1132200) results in an amino acid change from alanine to threonine at position 487 of the protein. Although almost no biological data have been published suggesting its relevance to SLE, it has been found to be associated with multiple sclerosis. ⁷⁹⁾ |
| Bates et al. 2009 ⁸⁰⁾ | <i>TNFAIP3</i> | rs5029939 | Caucasian 2 (MG) | G<T | 2.09 (1.68-2.60) | 1.67×10 ⁻¹⁴ | The tumor necrosis factor alpha inducible protein 3 (<i>TNFAIP3</i>) encodes the ubiquitin-modifying enzyme A20 and is an inhibitor of nuclear factor-κB activity in several signaling pathways, including those of TNF and Toll-like receptors. Also, it is required for the negative regulation of inflammatory responses. ⁸¹⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>TNFAIP3</i> | rs6932056 | European 2 (MG) | C<T | 1.83 (1.65-2.02) | 1.97×10 ⁻³¹ | |
| Ramos et al. 2011 ⁷⁴⁾ | <i>TNFSF4</i> | rs10798269 | Overall 4 (MG) | A<G | 0.83 (0.78-0.88) | 4.04×10 ⁻¹⁰ | <i>TNFSF4</i> gene encodes a cytokine of the TNF ligand family. The encoded protein functions in T-cell APC interactions and mediates adhesion of activated T cells to endothelial cells. ³⁸⁾ |
| Sheng et al. 2015 ⁵⁰⁾ | <i>TNFSF4</i> | rs1418190 | Chinese 2 (MG) | C<T | 0.81 (0.75-0.87) | 1.08×10 ⁻⁸ | |
| Sheng et al. 2015 ⁵⁰⁾ | <i>TNFSF4</i> | rs4916219 | Chinese 2 (MG) | A<G | 0.80 (0.75-0.86) | 7.77×10 ⁻⁹ | |
| Bentham et al. 2015 ³⁵⁾ | <i>TNFSF4</i> | rs704840 | European 2 (MG) | G<T | 1.22 (1.17-1.27) | 3.12×10 ⁻⁹ | |
| Yang et al. 2017 ⁸²⁾ | <i>TNF-α</i> | rs1800629 | Overall 41 (MO) | A vs. G | 1.70 (1.46-1.98) | <0.001 | TNF is a pleiotropic cytokine that produces different stimuli in various physiological and pathological conditions. TNF contributes importantly to the development of T cells, B cells, and DCs. ⁴⁷⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>TNIP1</i> | rs10036748 | European 2 (MG) | C<T | 1.38 (1.32-1.45) | 1.27×10 ⁻⁴⁵ | <i>TNIP1</i> gene encodes an A20-binding protein which plays a role in autoimmunity and tissue homeostasis through the regulation of nuclear factor kappa-B activation. ³⁸⁾ |
| Wang et al. 2013 ⁵⁴⁾ | <i>TNIP1</i> | rs7708392 | Caucasian 3 (MG) | C/G | 1.29 (1.17-1.44) | 1.2×10 ⁻⁶ | |
| Lee et al. 2012 ⁴⁷⁾ | <i>TNPO3</i> | rs12531711 | European 2 (MG) | G<A | 1.593 (1.403-1.808) | 6.41×10 ⁻¹³ | <i>TNPO3</i> is a nuclear import receptor for serine/arginine-rich (SR) proteins, which are essential precursor-mRNA splicing factors. ⁸³⁾ |
| Kurreeman et al. 2010 ⁸⁴⁾ | <i>TRAF1-C5</i> | rs10818488 | Overall 3 (MG) | A | 1.22 (1.12-1.31) | 1.02×10 ⁻⁶ | <i>TRAF1</i> is involved in the negative regulation of T-cell proliferation and serves as an essential effector of the TNF signaling cascade. <i>C5</i> is known to be a factor in the complement cascade and may increase susceptibility to autoimmune and inflammatory disease. ⁸⁵⁾ |

Table 2. Noteworthy genetic variants and their functions (Continued)

| Study | Gene | Variant (RS number) | Ethnicity, study No. (types of study) | Comparison | OR (95% CI) | P value | Function of genes |
|---------------------------------------|-----------------|---------------------|---------------------------------------|------------|------------------|------------------------|--|
| Namjou et al. 2012 ⁸⁶⁾ | <i>TRAF6</i> | rs4755453 | Overall 4 (MO) | C vs. G | 0.88 (0.83-0.94) | 4.73×10 ⁻⁵ | <i>TRAF6</i> encodes an adaptor molecule that has a central role in the nuclear factor NF-κB activation pathway. It regulates inflammation, DC development, thymic selection and regulatory T-cell production as well as osteoclast formation. |
| Namjou et al. 2012 ⁸⁶⁾ | <i>TRAF6</i> | rs5030437 | Overall 4 (MO) | A vs. G | 0.88 (0.83-0.94) | 7.85×10 ⁻⁵ | |
| Namjou et al. 2012 ⁸⁶⁾ | <i>TRAF6</i> | rs5030445 | Overall 4 (MO) | A vs. G | 0.88 (0.83-0.94) | 1.31×10 ⁻⁴ | |
| Namjou et al. 2012 ⁸⁶⁾ | <i>TRAF6</i> | rs5030472 | Overall 4 (MO) | A vs. G | 0.85 (0.77-0.92) | 4.75×10 ⁻⁴ | |
| Bentham et al. 2015 ³⁵⁾ | <i>TYK2</i> | rs2304256 | European 2 (MG) | A<C | 1.24 (1.17-1.31) | 3.50×10 ⁻¹³ | <i>TYK2</i> gene encodes a member of the tyrosine kinase and, more specifically, the JAKs protein families. This protein associates with the cytoplasmic domain of type I and type II cytokine receptors and promulgate cytokine signals by phosphorylating receptor subunits. It is also component of both the type I and type III interferon signaling pathways. ³⁸⁾ |
| Diaz-Gallo et al. 2013 ⁸⁷⁾ | <i>UBASH3a</i> | rs9976767 | Overall 2 (MO) | G vs. A | 1.23 (1.11-1.37) | 2.4×10 ⁻⁴ | <i>UBASH3</i> gene encodes one of 2 family members belonging to the T-cell ubiquitin ligand family. Both family members can negatively regulate T-cell signaling. ³⁸⁾ |
| Ramos et al. 2011 ⁷⁴⁾ | <i>UBE2L3</i> | rs181359 | Overall 4 (MG) | T<C | 1.23 (1.15-1.33) | 1.15×10 ⁻⁹ | The modification of proteins with ubiquitin is an important cellular mechanism for targeting abnormal or short-lived proteins for degradation. This gene encodes a member of the E2 ubiquitin-conjugating enzyme family. It participates in the ubiquitination of p53, c-Fos, and the NF-κB precursor p105 <i>in vitro</i> . ³⁸⁾ UBE2L3 participates in ubiquitylation and has a key role in the regulation of innate and adaptive immune systems. ⁸⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>UBE2L3</i> | rs7444 | European 2 (MG) | T<C | 1.27 (1.21-1.33) | 1.84×10 ⁻²² | |
| Bentham et al. 2015 ³⁵⁾ | <i>UHRF1BP1</i> | rs9462027 | European 2 (MG) | A<G | 1.14 (1.09-1.19) | 7.55×10 ⁻⁹ | UHRF1 binding protein 1 |
| Sheng et al. 2015 ⁵⁰⁾ | <i>ULK3</i> | rs881536 | Chinese 2 (MG) | A/C | 1.16 (1.07-1.23) | 5.78×10 ⁻³ | The kinase domain of ULK3 was required for reporter activation. ULK3 showed autophosphorylation activity, and it showed serine/threonine kinase activity toward GLI2, with lower kinase activity toward GLI1 and GLI3. ⁸⁹⁾ |
| Zhou et al. 2014 ⁹⁰⁾ | <i>VDRr</i> | rs2228570 | Overall 6 (MO) | F vs. F | 0.75 (0.65-0.86) | <0.0001 | <i>VDRr</i> gene encodes vitamin D3 receptor, which is a member of the nuclear hormone receptor superfamily of ligand-inducible transcription factors. Downstream targets of vitamin D3 receptor are principally involved in mineral metabolism, though this receptor regulates a variety of other metabolic pathways, such as those involved in immune response and cancer. ³⁸⁾ |
| Bentham et al. 2015 ³⁵⁾ | <i>WDFY4</i> | rs2663052 | European 2 (MG) | G<A | 1.16 (1.10-1.22) | 5.25×10 ⁻⁹ | WDFY4 is a huge protein with unknown function but is predominantly expressed in primary and secondary immune tissues. |
| Zhang et al. 2015 ⁹¹⁾ | <i>YDJC</i> | rs2298428 | Overall 3 (MG) | T<C | 1.23 (1.16-1.3) | 1.31×10 ⁻¹¹ | The role of the <i>YDJC</i> gene is currently largely unknown. ⁸⁸⁾ |
| Morris et al. 2016 ⁴²⁾ | <i>ZFP90</i> | rs1170426 | Overall 3 (MG) | C | 1.12 (1.08-1.17) | 2.24×10 ⁻⁸ | <i>ZFP90</i> gene encodes a member of the zinc-finger protein family that modulates gene expression. The encoded protein derepresses the transcription of certain fetal cardiac genes and may contribute to the genetic reprogramming that occurs during the development of heart failure. ³⁸⁾ |

OR, odds ratio; CI, confidence interval; MG, meta-analysis of genome-wide association studies; MO, meta-analysis of observation studies.

(*Arabidopsis thaliana*, *Caenorhabditis elegans*, *Danio rerio*, *Drosophila melanogaster*, *Escherichia coli*, *Homo sapiens*, *Mus musculus*, *Rattus norvegicus*, and *Saccharomyces cerevisiae*). It provides a comprehensive compiled network from hundreds of different sources such as coexpression, genetic interactions, colocalization information, and shared protein domains. GeneMANIA utilizes linear regression models to combine different functional association networks from multiple data sources and Gaussian field label propagation methods are applied to predict the gene function based on composite functional networks. The combined edge scores are calculated as the weighted sum of scores by em-

phasizing the directly connected genes.

2. STRING database

The STRING 9.1 network database³²⁾ is one of the largest databases of direct (physical) PPI and indirect (functional) interactions constructed from various data sources. The STRING database covers 9.6 million proteins from 2,031 different organisms and incorporates PPI information from a number of known databases, such as Reactome, KEGG pathways, HPRD, BioGrid, and MINT as well as automated text mining including PubMed abstracts and OMIM database. It also includes com-

putationally predicted PPI by utilizing ortholog information between different species. The STRING database provides the PPI score using a naïve Bayesian algorithm to combine different scores from different biological evidence with a correction for random observation probability of interactions. Thus, the combined STRING edge score is used to indicate strong confidence for such PPI.

3. Construction of PPI networks using the STRING database

In our study, we used the STRING database to identify the PPI associated with gene mapping to genetic variants of SLE. First, our gene lists represented by gene symbol were converted to Ensembl protein identifiers using mapping information from the NCBI ftp server. Some of the gene symbols were preprocessed for conversion to official gene symbols before Ensembl ID mapping due to their ambiguity. Based on given Ensembl protein identifiers and the minimum PPI score, each PPI is extracted from the STRING databases. Depending on interests, we also extracted the closely associated genes with current gene lists using the Random Walk with Restart Algorithm,³³⁾ where functional closeness of 2 gene lists is represented by an XD score using the STRING database. We applied our in-house program written with Perl and C. Once the functionally related genes are selected, Cytoscape,³⁴⁾ which is a free software package for visualizing, modeling, and analyzing molecular and genetic interaction networks, is used for network visualization. To import the PPI file into Cytoscape, users must prepare the network input file constructed from at least 3 columns: source node, interaction type, and target node. Edge attributes such as interaction score can also be imported into the network. The node property file can be prepared to indicate any property of each gene/proteins such as name, function, and node type (i.e., node data source). These 2 files (i.e., network file, node property file) were imported into Cytoscape for the visualization.

4. PPI network for SLE

Here we constructed the PPI network with genes mapping to the compiled reported genetic variants of SLE. Fig. 3A represents the PPI networks with genes having genetic variants with statistical significance from observational studies. Among the 135 genetic variants mapping to 79 genes, 54 genes revealed 846 interactions between them and *IL-6*, *TP53*, *IL-10*, *ITGAM*, and *NFKB1* were identified as strong hub nodes. In addition, *TRAF6*, *IRF5*, *ITGAM*, *TNFAIP3*, and *BLK* were identified as critical genes having more than 4 reported genetic variants in SLE, which shows a strong association of such genes with SLE. Fig. 3B and 3C also show the PPI networks with statistically significant and borderline genes from GWAS studies (i.e., $P < 5 \times 10^{-8}$, $5 \times 10^{-8} < P < 0.05$), respectively. *TNFSF4*, *CD44*, *STAT4*, and *TNFAIP2* also showed a strong association with SLE from GWAS studies. Moreover, *PTPRC*, *STAT4*, and *IL-10* also revealed strong hubness in the PPI network.

Next, we integrated these PPI networks with the genes mapping to overall genetic variants of SLE from 3 criteria. As shown in Fig. 4, genes from observational studies, GWAS with 2 different *P* values, are closely connected within the PPI network. Many genes have genetic variants identified from at least 2 studies (i.e., orange, green, and purple nodes). Among the 148 genes, 97 revealed 1,554 PPI. Interestingly, *TP53*, *PTPRC*, *NFKB1*, *IL-6*, *IL-10*, and *STAT4* have more than 60 interactions in the PPI network and *IL-10*, *STAT4*, *ITGAM*, *FCGR2A*, and *PTPN22* are also identified as genes having genetic variants in SLE from both observational and GWAS.

Discussion

In this review, we provided general concepts for applying Bayesian methods and gene network analyses to interpret genetic

Fig. 3. PPI network with genes mapping to the statistically significant genetic variants. (A) Statistically significant genes from observational studies (T1: $P < 0.05$), (B) statistically significant genes (T2: $P < 5 \times 10^{-8}$) from GWAS, (C) statistically significant genes at the borderline (T3: $5 \times 10^{-8} < P < 0.05$) from GWAS. Node size represents the number of interactions, while edge width represents the PPI score from the Retrieval of Interacting Genes/Proteins) databases. The width of interactions shows the strength of the interactions mapping to the STRING score. PPI, protein-protein interactions; GWAS, gene-wide association studies.

Fig. 4. Compiled PPI network with genes mapping to the genetic variants identified using different criteria. The node color of genes represents the evidence for genetic variants mapping to genes. Red indicates genes from observational studies (T1), yellow indicates statistically significant genes from GWAS (T2), and blue indicates borderline significant genes from GWAS (T3). Orange, green, and purple genes are genetic variants of SLE identified from at least 2 criteria (T1 and T2, T2 and T3, and T1 and T3, respectively). Note that miR-146a is identified from all 3 criteria (T1, T2, and T3) but not shown in the PPI network. PPI, protein-protein interaction; GWAS, genome-wide association study.

epidemiology results. The Bayesian approach is unfamiliar in genetics and the need for filtering true-positive or “noteworthy” genetic variants is unavoidable due to the enlarging amount of research data. Although a meta-analysis provides one of the highest levels of evidence within research in the medical field, different meta-analyses from different groups must be integrated and rehighlighted. We refined scattered positive data of meta-analyses in SLE with discovering false-positive results using Bayesian approaches, FPRP and BFDP, consequently suggesting a comprehensive PPI for the disease.

The Bayesian approach and its value depend on the prior probabilities, the calculation of power ($1-\beta$), and the probability of type I error (α). FPRP has been criticized for its heuristic derivation of α and $1-\beta$ as $P_0(t)$ and $P_\delta(t)$, for which $P_0(t)$ is the probability of observing a value greater than $|t|$ or less than $-|t|$ under the null hypothesis, versus $P_\delta(t)$ under the alternative; in other words, α and $1-\beta$ are pre-study quantities as properties of a test, while $P_0(t)$ and $P_\delta(t)$ are post-study parameters,²² in fact, not related to the test genuine parameters. Also, FPRP calculates its likelihood with its tail-area; thus, information is lost compared to BFDP, in which the exact ratio of the probability densities in the indicated point is calculated. Still, both assessments are recommended in a study to determine the true impact of the discovery.

Our gene network construction with genes having noteworthy genetic variants found sound PPI in SLE. The hub genes with more than 50 interactions were *PTPRC*, *TP53*, *NFKB1*, *IL6*, *STAT4*, *IL10*, *IITGAM*, *TLR7*, *IFNG*, *IL1B*, *FCGR2A*, *JAK2*, *CD40*, *FCGR3A*, *PTPN22*, *RANTES*, *ICAM1*, *IRAK1*, *FCGR2B*, *CD80*, *IL18*, and *TNFAIP3*.

The PPI construction using the STRING database provides

insight for further wet lab-based research. On the other hand, although observational studies or GWAS elicited statistically significant genetic variations, they might not reveal the actual biological mechanism until epigenetic or molecular changes are proven. To overcome this hurdle, a combination analysis of gene expression and the matching SNP profile may be the way forward for discovering the disease etiology.

Conflicts of interest

No potential conflict of interest relevant to this article was reported.
